In making these experiments the outlets of the filters were in most instances opened quickly and allowed to remain open, but occasionally, as with Filter No. 43 on November 9, the faucet was opened quickly, allowed to remain so for a few minutes and then closed to its original position. The experiments were all made during the months of October and November, and during October the number of bacteria in the applied canal water was unusually high. On October 10, the day on which the rate of Filter No. 33 was first fluctuated, as given in the table, the number of bacteria in the applied canal water was 298,000, and on October 9, the day on which the rate of Filter No. 48 was first fluctuated, the number in the canal water was 126,000 per cubic centimeter.

### *High Rates of Filtration.*

The longer the investigations upon water filtration have been continued, the more evident it has become that entirely satisfactory bacterial purification of water can be obtained at rates of filtration much greater than formerly supposed. If the results obtained at the station during the past two or three years have decided anything they have certainly made this point clear. It has also been decisively settled that the bacterial efficiency of natural sand filters increases with age, and that a growing municipality that decides to filter its water supply through sand can reckon upon increasing the volume of water filtered through a given area of filter bed as the filter grows older, and obtain a bacterial efficiency equal to that obtained at the beginning of operation of its filter. Entirely satisfactory results were obtained during 1895 from filters operating at rates of 5,000,000 and even 7,000,000 gallons per acre daily. The results from filters Nos. 3 B and 8 A have been mentioned on previous pages, and the average bacterial efficiency of all the filters, together with their rates of operation, have been given in the first table of this report.

Increasing the rates of individual filters from year to year has not resulted in decreased bacterial efficiency, but the increase of period of service of these filters has been partly accountable for the entirely satisfactory results obtained. An interesting experiment has been made with filters Nos. 48 and 49. These two filters each contain approximately 5 feet in depth of sand of an effective size of 0.38 millimeter and were constructed at the same time. During 1894 and 1895 Filter No. 49 has been operated at a rate approximately

twice as great as the rate of operation of Filter No. 48, and the bacterial efficiency of these two filters, together with their rate of filtration, is given in a following table. The results are interesting as showing that a filter can be operated at a rate of more than 9,000,000 gallons per acre daily and maintain an average bacterial efficiency of more than 99 per cent.

There is one instance recorded which deserves explanation. During October, 1895, the average number of bacteria in the effluent of Filter No. 49 was 533. In order to maintain the high rate of filtration it was necessary to scrape this filter very frequently during October, and as the average number of bacteria in the applied canal water was unusually high on several occasions, they caused high numbers in the effluent. For instance, on October 3 there were 319,000 bacteria per cubic centimeter in the applied water and 2,086 in the effluent. On October 9, 12 and 15 the filter was scraped, and on these days there were 126,000, 147,000 and 17,000 bacteria per cubic centimeter in the applied water and 1,050, 4,753 and 152 bacteria per cubic centimeter in the effluent.

The filter at this time was running at an average rate of filtration of nearly 10,000,000 gallons per acre daily. Filter No. 48, operating at a rate of 5,000,000 gallons per acre daily, was much less affected by these high numbers of bacteria in the applied water.

*Table to show the Relative Efficiency of Filters operating at High, as compared with those operating at Lower, Rates of Filtration.*

Nearly all of the filters have been operated during 1895 at rates which would have formerly been considered abnormally high, but the good and uniform bacterial efficiency obtained at these high rates of filtration certainly go to prove that, in estimates of the cost of construction of natural sand filter beds, rates of filtration equal to four or five million gallons per acre daily can be considered safe with water of about the character of that of the Merrimack River.

*The Effect of the Method of Application of Water to the Filters upon Bacterial Efficiency.*

There have been in operation at the station during 1895 fourteen continuous and five intermittent water filters. To all of these filters Merrimack River water, containing a large percentage of dissolved oxygen, has been applied, and none of the filters which have contained more than 12 inches in depth of filtering material and were in operation during 1894 have given a bacterial efficiency of less than 98.74 per cent. The method of operating the intermittent filters was the same as during 1894, and as follows: at 6.30 A.M. the application of water was stopped and the filter allowed to drain for two hours from the time when the surface was first uncovered; water was then again applied and the gate of the outlet pipe kept constantly open. Operating in this way, the air drawn into the filter while the surface was uncovered and the filter was draining was largely forced downward through the outlet and much surface disturbance prevented. Taking intermittent Filter No. 3 B and its continuous mate, Filter No. 8 A, both of which were operated throughout the entire year, we find that Filter No. 8 A has given the greatest bacterial efficiency. Upon a comparison of their efficiency during different seasons of the year it is found that during weather when the temperature of the day is not, or but slightly, below the freezing point, Filter No. 3 B has given an efficiency nearly or quite equal to Filter No. 8 A. During freezing weather, however, the exposure of the surface of Filter No. 3 B has resulted in decreased efficiency at times.

*Table showing Comparative Bacterial Efficiency of Intermittent and Continuous Filters at Different Seasons of the Year.*

*Method of Putting Filters into Operation after Scraping.*

It has been the custom during the year, with the large out-door filters Nos. 3 B, 7 A and 8 A, after scraping to remove clogging, to rake the surface of the filter to a depth of 1 inch and then fill the filter slowly from below with city filtered water. The filters have then been allowed to rest for a number of hours with their surface covered with water before starting filtering again. The small iron filters, after scraping to remove clogging, have been started without raking and with canal water applied from above. The better bacterial results are obtained by the first treatment. Of the thirteen scrapings of Filter No. 3 B, ten had no appreciable effect upon the number of bacteria in the effluent, and of the seventeen scrapings of Filter No. 8 A, sixteen had no appreciable effect upon the number of bacteria in the effluent.

On Oct. 28, 1894, Filter No. 3 B was spaded over to a depth of about 6 inches for experimental purposes, and the bacterial results following this treatment are given in a table in the report of the Board for 1894, which is here repeated. The filter, after this spading over, was started by applying canal water from above.

| 4, . . .           | -          | 346       | Surface clogged again.                                                                                        |
| 5, . . .           | -          | 339       |                                                                                                               |

The average number of bacteria in the applied river water during this period was about 12,000 per cubic centimeter.

On Oct. 23, 1895, Filter No. 3 B, while operating at the same rate as in November, 1894, was again spaded over to a depth of 6 inches, but was put in operation after this treatment by filling it slowly from below with city filtered water and then allowing it to stand with its surface covered with water for two hours before again turning on the river water and opening the outlet gate. The bacterial results subsequent to this treatment are given in the following table:—

*Bacteria per Cubic Centimeter in Effluent of Filter No. 3 B.*

| 1895.                 | Hour.      | Bacteria. | Remarks.                                                              |

| 31, . . . . .         | -          | 15        |                                                                       |

Bacteria in the applied water during this period averaged 3,000 per cubic centimeter.

*Summary of Results of Scraping Water Filters.*

The following table summarizes the results obtained during the year in regard to the volume of water filtered between scrapings, and the approximate depths of sand removed at each scraping, for all filters whose depth remained practically the same throughout their period of operation.

*Summary of Results of Scraping Water Filters during 1895.*

| NUMBER OF FILTER. | Effective Size of Sand. (Millimeters.) | Approximate Depth of Sand. (Inches.) | Maximum Loss of Head. (Inches.) | Rate. (Gallons per Acre Daily.) | Method of Operation. | Average Depth of Sand removed at Each Scraping. (Inches.) | Average Quantity of Water filtered between Scrapings. (Gallons per Acre.) |

**CHEMICAL PURIFICATION BY FILTRATION.**

All of the suspended organic matter in the applied river water is removed by filtration and a large but variable amount of the soluble organic and coloring matters. During 1894 the average removal of color was 43 per cent., of albuminoid ammonia 55 per cent., and of oxygen consumed 44 per cent. of that in the unfiltered Merrimack River water. These results were better than those obtained during 1893 and also better than the results obtained during 1895, as shown by the following table. A summary of this table shows that the filters have removed during 1895, 30 per cent. of the color, 52 per cent. of the albuminoid ammonia and 26 per cent. of the oxygen consumed in the applied river water. The better results obtained upon the removal of color and oxygen consumed during 1894 were probably due to the fact that at the beginning of 1894 the filters were filled to their original height with new sand, and the experience of the station has been that most varieties of sands have the greatest efficiency in regard to the removal of color during the beginning of their period of use for filtration. The removal of albuminoid ammonia was practically the same as during 1894. The results for these two years indicate that old filters are as efficient as new in removing that organic matter determined as albuminoid ammonia. With the applied Merrimack River water, always containing a considerable percentage of dissolved oxygen, there was practically no difference during the year between the results obtained by intermittent as compared with continuous filtration, and dissolved oxygen has invariably been present in the effluents of the various filters, with the exception of the effluent of Filter No. 48, during a portion of September. This filter was operating at this time at a rate of 10,000,000 gallons per acre daily.

Table showing Percentages which the Color, Albuminoid Ammonia, and Oxygen consumed in the Effluents were of those in the Applied Water.

*The Water taken from the Merrimack River and applied to the  
Experimental Filters.*

All the water applied to the filters during 1895 has been Merrimack River water, taken from the Essex Company's canal. During a large part of the year an abundant supply was obtained through a 12-inch iron pipe connected with the locks at the foot of the canal. This pipe is above the ground and cannot be used during winter weather, and for this reason our supply of water is more limited during cold weather, when we are dependent upon the water obtained through a 4-inch pipe from the same canal.

The results of the analyses of the water as it flows upon the filters at the station are given in the next two tables; the first giving the average daily results of two or more bacterial determinations and the second giving the monthly averages of the chemical analyses. With the latter table are given the results of bacterial analyses of samples taken at the same time that the samples for chemical analysis were taken. Their average is of course not identical with the average results of the preceding table.

Average of Daily (8 A.M. and 4 P.M.) Number of Bacteria per Cubic Centimeter in Canal Water, 1895.

*Solids in the River Water during a Freshet.*

The following table records the solids in the water of the Merrimack River in April, 1895, during a period of severe freshet. The river water was very turbid, caused by a large amount of silt in suspension in it. The rapidity with which this silt settles is shown by the determinations of the solids, as given in the table, after the water had been allowed to stand in a gallon bottle for twenty-four hours, and also by allowing the water to stand in a 6-foot tube for different periods, as given in the table.

The total solids in the water on April 16 were 111 parts per 100,000 parts, and samples were taken from the river daily until April 25, when the water had returned to very nearly its normal condition.

*Solids in Merrimack River Water during the Freshet of April, 1895.*

*Application of Bacillus Prodigiosus.*

*Bacillus prodigiosus* has been applied, together with the river water from the canal, to filters 3 B, 7 A, 8 A, 43, 44, 45, 48, 49, 62, 63 and 64 at different periods from March to November. The general plan of the experiments has been the same as in previous years (see annual report of the Board for 1892, page 529), except that the germ has been applied in smaller numbers. A pure culture of *B. prodigiosus* has been obtained by inoculation and growth for four days at 20° C. in a solution of one-tenth per cent. peptone and two-tenths per cent. glucose in city water. This mixture has been applied to the filters in the proportion of 1 part mixture to 170,000 parts of water, at intervals of one hour for ten hours a day and six days in a week.

Numerous examinations have been made at frequent intervals to determine whether or not this germ passed through the filters.

In order to strengthen the regular method of determination a number of tests were made (by using a large roll-tube) by which 50 cubic centimeters of effluent could be examined at a time. It is interesting to note that in no single instance in which the effluent

of Filter No. 8 A was examined by this method did a single *B. prodigiosus* appear.

In the next table are given the average numbers of *B. prodigiosus* per cubic centimeter in the applied water for ten hours during each day that this germ was applied to the filters.

*Average Number per Cubic Centimeter of Bacillus Prodigiosus in Applied River Water for Ten Hours Daily, 1895.*

DETAILED ACCOUNT OF THE WORK OF THE SEVERAL WATER  
FILTERS IN 1895.

The remainder of this report upon water filtration contains a brief account of the construction and operation of each filter, the average results of daily bacterial analyses and the monthly averages of chemical analyses, together with the average bacterial results of samples taken at the same time the samples for chemical analyses were taken. The daily bacterial results are made up by averaging the results of several daily analyses in the case of filters Nos. 3 B, 7 A and 8 A.

All the in-door filters were, for reasons previously given, not operated from Dec. 1, 1894, until the spring of 1895, and all the filters were at times subjected to treatment not necessarily a part of filtration.

*Filter No. 3 B.*

This intermittent filter was started Sept. 23, 1893, and contained 60 inches in depth of sand of an effective size of 0.23 millimeter. The history of this filter up to Jan. 1, 1895, has been published in the annual reports of the Board. Its history during 1895 contained the following principal points.

In order to prevent the upper layers of sand from freezing during the period of intermittent operation, the gate in the canal water pipe was closed at 5 A.M. As a result of this procedure the surface of the sand became and remained uncovered for two hours during the warmest part of the day. From Dec. 29, 1894, to March 8, 1895, the prescribed rate of filtration was 1,500,000 gallons per acre daily. On March 11 this rate was increased to 5,000,000 gallons. The filter continued in operation at this rate until November 24, when the rate was decreased to 1,500,000 gallons per acre daily. On Sundays and on days following scrapings the filter ran continuously. As the water in the feed-pipe froze, the gate on the outlet was closed and the surface of the sand remained uncovered with water from February 6 to 13. High water in the river made it necessary to shut the valve again from April 11 to 13, and from April 14 to 19, though the surface of the sand was covered with water. The river silt was scraped from the surface April 20, and city water applied slowly from below on the 22d. After the surface became covered

the filter was allowed to stand full of water for forty-eight hours, and started at the usual rate April 28. On account of low water in the canal the gate on the outlet remained closed, and the surface of the sand covered with water on the following dates: March 10, 30, April 27, May 5, June 8, 16, 23, July 6, 13, 21, 25, August 3, September 22, 28 and November 23, for periods varying from twelve to thirty-six hours.

A short trap was attached to the outlet, but the lower foot of sand was not saturated. In order to remove clogging the filter was filled with city water from below on December 26, and the surface was raked to a depth of 1 inch on January 8. To remove clogging more efficiently the filter was scraped as follows: 1 inch of sand was removed on March 9 and 26;  $\frac{1}{2}$  inch (approximately) of sand was removed on June 25, July 31, August 26, October 1, 16, 23, November 7 and 18. After scraping, the filter was, on each occasion, raked to a depth of 1 inch, except on October 23, when it was spaded to a depth of 6 inches. On March 29 the filter was restored to its original height with new sand, after scraping. Before applying canal water the filter was filled with city (filtered) water slowly from below after scraping and allowed to stand for several hours.

A solution seeded with *Bacillus prodigiosus* was mixed with the applied canal water, in the ratio of 1 part to 170,000 parts, for ten hours a day, from March 11 to April 10, and from September 2 to November 21. Four samples of effluent collected at different hours each day (excepting Sunday) have been analyzed. Averages of these analyses, calculated for twenty-four-hour periods, are given in the following table:—

*Average Daily Number of Bacteria per Cubic Centimeter in Effluent of Filter  
No. 3 B, 1895.*

*Filter No. 7 A.*

This continuous filter was started July 20, 1894, and contained 24 inches in depth of sand of an effective size of 0.26 millimeter. Its history for the year 1894 has been published in the annual report of the Board. The principal features in the history of the filter during 1895 are as follows:—

After draining, the filter went out of operation for the winter on December 28, 1894. On March 24, 1895, it was filled slowly from below with city (filtered) water and allowed to stand for thirty-six hours. March 26 the filter began to filter canal water continuously at a prescribed rate of 2,000,000 gallons per acre daily. This rate was increased permanently, on May 1, to 5,000,000 gallons. July 1, for a period of sixteen hours, the filter ran at a rate of 5,250,000 gallons. A trap was attached to the filter so that the point of delivery was nearly opposite to the outlet. Owing to high water the gate on the outlet remained closed from April 10 to 13, and the surface of the sand covered with water. The gate was opened April

13 and remained open for thirty-four hours, but was closed again in consequence of high water. On April 19 the gate was opened and the filter allowed to drain until the 24th. Several inches of river silt were scraped from the surface on the 20th. City (filtered) water was applied slowly from below on April 24, until it covered the surface of the sand. Having stood full of water over night, the filter again went into operation on April 25 at the prescribed rate (5,000,000 gallons per acre daily). In consequence of low water in the canal the gate on the outlet remained closed, and the surface of the sand covered with water, for periods varying from eight to twenty-seven hours, on the following dates: March 30, April 27, May 5, June 8, 16, 23, July 6, 13, 21, August 3 and November 23.

In order to remove clogging at the surface, one-half an inch (approximately) of sand was removed from the surface of the filter by scraping on May 16, June 4, 26, July 17, August 7, 27, September 7, 26, October 12, 23, November 12 and 23. After scraping, the filter was raked to a depth of 1 inch, and then filled slowly with city (filtered) water from below. After filling with city water and before turning on the canal water the filter was allowed to stand for a period varying from eight to eighteen hours. Attention is called to the fact that this filter was scraped frequently to remove clogging during 1895, instead of being simply raked, as in 1894. After draining, the filter went out of operation November 25.

To test the bacterial efficiency of the filter four samples of effluent have been collected daily at different hours (Sundays excepted) and analyzed. Averages of these hourly samples, calculated for the whole period of twenty-four hours, are given in the record of daily analyses in the following table. A solution seeded with *Bacillus prodigiosus* was applied to the filter in the ratio of 1 part to 170,000 of the applied canal water from August 20 to November 19. A few of these organisms appeared in the effluent occasionally, as indicated in the table.

*Average Daily Number of Bacteria per Cubic Centimeter in Effluent of Filter

*Filter No. 8 A.*

This continuous filter was started Sept. 26, 1893, and contained 60 inches in depth of sand of an effective size of 0.23 millimeter. The history of this filter up to Jan. 1, 1895, has been published in previous reports of the Board. The principal features in its history during 1895 are presented in the following paragraphs.

From Dec. 29, 1894, to March 11, 1895, the prescribed rate of filtration was 1,500,000 gallons per acre daily. On March 12 the rate was increased to 5,000,000 gallons. The filter continued in operation at this rate until November 25, when the rate was decreased to 2,000,000 gallons per acre daily. A trap was attached to the outlet. On January 31 the feed-pipe froze, and the filter remained out of service, with the surface of the sand uncovered with water, from February 1 to 6. On the 7th, city (filtered) water was applied from below until the surface became covered. After standing full of water over night the filter was started February 8. Owing to high water in the river the filter remained out of regular service from April 10 to 13, the surface of the sand being covered with water. The outlet was opened on the 13th and remained open for thirty-four hours. The filter was drained on the 19th; the river

silt was removed on the 20th; city water applied from below on the 21st until the surface was covered and the filter was then allowed to rest until the 26th. In consequence of low water in the canal the gate on the outlet remained closed and the surface covered with water on March 30, April 27, May 5, June 8, 16, 23, July 6, 13, 21, 25, August 3, 28, September 23, 28 and November 22, for periods varying from eight to thirty-six hours.

In order to remove clogging, 1 inch of sand was scraped from the surface of the filter on January 25, March 11 and 27.

After scraping on March 27 the filter was restored to its original depth with fresh sand. One-half an inch (approximately) of sand was removed by scraping on May 9, 23, June 11, 29, July 16, August 2, 20, September 2, 18, October 4, 17, 28, November 12 and December 18. After scraping, the filter was raked 1 inch deep, filled slowly with city (filtered) water from below, and allowed to stand with the surface covered by water, for periods varying from nine to thirty-four hours. On May 9, for purposes of experiment, the filter was filled with canal water from above after scraping. As the surface was found to be uncovered on February 1, 6, September 22 and December 16, city water was applied from below and the filter allowed to stand full of water for several hours. On November 10 the surface of the filter was spaded 6 inches deep.

A solution seeded with *Bacillus prodigiosus* was mixed with the applied canal water in the ratio of 1 to 170,000 parts for ten hours a day (excepting Sundays) from March 11 to April 10 and from May 6 to November 19; and in the proportion of 1 part to 85,000 parts from November 21 to December 1. Several samples were collected for bacterial analyses daily (excepting Sundays) from the effluent. Averages of these determinations, calculated for twenty-four-hour periods, will be found in the record of daily analyses in the following table:—

Average Daily Number of Bacteria per Cubic Centimeter in Effluent of Filter No. 8 A, 1895.

*Filter No. 18 A.*

This intermittent filter, 20 inches in diameter, was started Sept. 17, 1889, and contained 62 inches in depth of sand of an effective size of 0.48 millimeter. The history of this filter up to Dec. 31, 1894, has been published in previous reports of the Board. The principal points in its history during 1895 are as follows:—

From Dec. 1, 1894, to April 30, 1895, the filter was not operated. On May 1, after having been filled slowly from below with city (filtered) water, it was put in operation at a prescribed rate of 5,700,000 gallons per acre daily. The depth of sand in the filter was 59 inches. The period of intermittent operation was arranged in such a manner that the surface remained uncovered for two hours during the day, excepting on Sundays, when the filter ran continuously. A trap was attached to the outlet in such a manner that the point of discharge was a little below the outlet and the lower layers of the filter were not kept saturated. Owing to a stoppage in the canal water pipe the surface of the filter was found to be uncovered, and no effluent running, on May 25, June 17 and July 26. In consequence of low water the filter was not in operation from fifteen to twenty hours on June 8, July 6, 13, August 3, September 22 and 28. During these periods the surface of the sand remained covered with water.

In order to remove clogging, the filter was scraped as follows: June 24, 0.63 inch in depth of sand was removed; August 16, 0.57 inch; August 31 enough sand was removed to reduce the total depth of filtering material to 3 feet; November 5, 0.73 inch. This filter was not raked and filled with city water from below, as in the case of No. 3 B, but, as in the cases of the other small filters, canal water was applied from above after scraping. On September 13 the rate of filtration was fluctuated by closing the gate in the outlet for a minute and then opening it quickly to the usual point. On November 2 and 22 the rate was fluctuated by throwing the gate wide open for one minute and then reducing the rate quickly to the original rate.

A solution seeded with *Bacillus prodigiosus* was mixed with the applied canal water, in the ratio of 1 part to 170,000 parts, for ten hours a day, from November 19 to 23. Samples of the effluent were analyzed daily (excepting Sundays and on certain other occasions), and the record of these daily bacterial analyses will be found in the following table:—

*Average Daily Number of Bacteria per Cubic Centimeter in Effluent of Filter No. 18 A, 1895.*

*Filter No. 33 A.*

This continuous filter was started April 28, 1892, and contained 60 inches in depth of sand of an effective size of 0.14 millimeter. The history of the filter up to Dec. 31, 1894, has been published in previous reports of the Board. The principal points for the year 1895 are as follows :—

From Dec. 1, 1894, to April 30, 1895, the filter was not in operation. On May 1, 1895, with a depth of sand of 58 inches, after having been filled slowly with city (filtered) water from below, the filter was put in operation at a prescribed rate of 2,000,000 gallons per acre daily. A trap was attached to the outlet. Owing to low water in the canal the filter was not in operation from twenty-four to thirty-nine hours on June 8, July 6, 13, August 3, September 22 and 28. For purposes of experiment the gate on the outlet pipe was closed for one minute and then opened to the original point on September 13, October 3 and 4. On October 10 the gate was thrown wide open for one minute and then closed to the usual point. The surface of the filter was scraped to remove clogging as follows : on June 24, 0.27 inch in depth of sand was removed from the surface ; July 6, 0.24 inch ; July 31, 0.26 inch ; August 16, 0.29 inch ; August 30, 0.30 inch ; September 21, 0.39 inch ; October 11, 0.27 inch ; October 24, 0.39 inch ; and November 19, 0.33 inch. After scraping, this filter was raked and filled with canal water from above and put in operation at once. A record of the daily (excepting Sundays) bacterial analyses will be found in the following table :—

*Average Daily Number of Bacteria per Cubic Centimeter in Effluent of Filter No. 33 A, 1895.*

*Filter No. 38.*

This continuous filter was started on April 28, 1892, and contained 24 inches in depth of sand of an effective size of 0.20 millimeter. The history of the filter up to Dec. 31, 1894, has been published in previous reports of the Board. The principal points in its history during 1895 are as follows:—

The depth of sand in the filter on Jan. 1, 1895, was 18 inches. From Dec. 1, 1894, to April 30, 1895, the filter was not in operation. On May 1, 1895, after having been filled slowly with city (filtered) water from below, the filter was put in operation at a prescribed rate of 1,000,000 gallons per acre daily. A trap was attached to the outlet. Owing to low water in the canal the filter was not in operation, for periods varying from thirty-four to thirty-nine hours, on June 8, July 6, 13 and August 3. The filter was allowed to stand full of water during these periods. In order to remove clogging the surface of the filter was scraped as follows: on July 31, 0.31 inch of sand was removed, and on August 21, 1 inch of sand was removed to show the effect of deep scraping. After scraping, the filter was not raked, but filled with canal water from above and put into operation at once. A sample of the effluent was collected daily (excepting Sundays) for bacterial analysis and the results are recorded in the following table:—

*Average Daily Number of Bacteria per Cubic Centimeter in Effluent of Filter  
No. 38, 1895.*

*Filter No. 41.*

This intermittent filter was started on May 9, 1892, and contained 60 inches in depth of sand of an effective size of 0.14 millimeter. Its history up to Dec. 31, 1894, has been published in previous reports of the Board. The principal points in its history during 1895 are as follows:—

The depth of sand on Jan. 1, 1895, amounted to 58 inches. From Dec. 1, 1894, to April 30, 1895, the filter was not in operation. On May 1, 1895, after having been filled slowly with city (filtered) water from below, the filter was put in operation, filtering canal water at a rate of 2,000,000 gallons per acre daily. From that date until November 23 the surface remained uncovered for two hours during each day, excepting Sundays, when the filter ran continuously. A trap attached to the outlet prevented air from passing into the filter at that point. Owing to low water in the canal the gate on the outlet remained closed and the surface of the sand covered with water on June 8, July 6, 13 and August 3, for periods varying from thirty-three to thirty-nine hours. The surface of the filter was scraped in order to remove clogging as follows: on June 4, 0.38 inch of sand was removed; on June 18, 0.23 inch; on June 27, 0.33 inch; on July 10, 0.43 inch; on July 22, 0.37 inch; on July 30, 0.45 inch; and on August 16, 0.39 inch. After scraping, the filter was not raked nor filled with city filtered water from below, but canal water was applied at the surface. A record of daily (excepting Sundays) bacterial analyses of the effluent will be found in the following table:—

*Average Daily Number of Bacteria per Cubic Centimeter in Effluent of Filter

*Filter No. 42.*

This continuous filter was started Oct. 29, 1892, and contained 10 inches in depth of sand of an effective size of 0.20 millimeter. The history of the filter up to Dec. 11, 1894, has been published in previous reports of the Board. Its history during 1895 contains the following points:—

From Dec. 1, 1894, to April 30, 1895, the filter was not in operation. On May 1, 1895, with only about 7 inches of fine sand, after having been filled slowly from below with city (filtered) water, filtration of canal water at a prescribed rate of 5,000,000 gallons per acre daily was begun. A short trap attached to the outlet prevented air from entering the filter at that point. Owing to low water in the canal the gate at the outlet remained closed and the surface of the sand covered with water on June 8, July 6, 13, August 3, and September 22 and 28, for periods varying from thirty-three to thirty-nine hours. The filter was scraped to remove clogging as follows: May 11, 0.27 inch of sand was removed; May 17, 0.21 inch; May 23, 0.32 inch; May 29, 0.29 inch; June 3, 0.30 inch; June 21, 0.30 inch; June 24, 0.27 inch; June 27, 0.21 inch; June 29, 0.34 inch; July 3, 0.27 inch; July 9, 0.29 inch; July 13, 0.24 inch; July 22, 0.33 inch; July 26, 0.32 inch; July 30, 0.24 inch; August 2, 0.30 inch; August 7, 0.24 inch; August 13, 0.24 inch; August 21, 1.36 inches; August 26, 0.30 inch; August 31, 0.26 inch; September 7, 0.35 inch; September 13, 0.28 inch; September 18, 0.24 inch; September 25, 0.24 inch; October 1, 0.17 inch; October 11, 0.24 inch; October 15, 0.20 inch; October 19, 0.30 inch; October 26, 0.26 inch; November 1, 0.30 inch; and November 11, 0.32 inch. The surface was not raked after scraping and the filter was usually filled with canal water from above; but on October 1 city water was applied from below.

This, in conjunction with the condition produced by the frequent scraping, which had reduced the fine sand to the under-drains, increased the number of bacteria in the effluent from that time on.

This is made evident in the following record of daily (excepting Sundays and on certain occasions when a sample was not taken) bacterial analyses of the effluent:—

*Average Daily Number of Bacteria per Cubic Centimeter in Effluent of Filter No. 42, 1895.*

*Filter No. 43.*

This continuous filter was started on May 30, 1893, and contained 60 inches in depth of sand of an effective size of 0.26 millimeter. The history of the filter up to Dec. 31, 1894, has been published in previous reports of the Board. Its history for 1895 contains the following principal points:—

From Dec. 1, 1894, to April 30, 1895, the filter was not in operation. On May 1, 1895, with a depth of fine sand equal to 57 inches, and after having been filled slowly from below with city (filtered) water, the filter began to filter canal water at a prescribed rate of 5,000,000 gallons per acre daily. A short trap attached to the outlet prevented air from entering the filter at that point. Owing to low water in the canal the gate on the outlet remained closed and the surface of the sand covered with water on June 8, July 6, 13, August 3, and September 22 and 28, for periods varying from twenty-four to thirty-nine hours. In order to remove clogging the surface was scraped as follows: on June 19, 0.20 inch of sand was removed; on June 27, 0.60 inch; on July 29, 0.38 inch; on August 1, enough sand was removed to reduce the total depth of filtering material to 36 inches; on August 27, 0.53 inch; on September 9, 0.50 inch; on September 20, 0.45 inch; on October 3, 0.39 inch; on October 16, 0.47 inch; on October 25, 0.49 inch; on November 7, 0.42 inch; on November 19, 0.49 inch. The surface was not raked after scraping and the filter was usually filled with canal water from above, but on August 1, October 25 and November 7, city (filtered) water was applied below.

The rate of filtration was fluctuated as follows: on September 7 and 30 the gate on the outlet was closed for one minute and then opened to the usual point; on October 7 the gate was thrown wide open for one minute and then closed to the usual point.

A record of the daily (excepting Sundays and on certain other days) bacterial analyses of the effluent will be found in the following table. It should be noted that, of the mixture of *Bacillus prodigiosus* which was applied to the filter in the ratio of 1 part of solution in 170,000 parts of applied water, a few cells occasionally appeared in the effluent.

*Average Daily Number of Bacteria per Cubic Centimeter in Effluent of Filter No. 43, 1895.*

*Filter No. 44.*

This continuous filter was started May 20, 1893, and contained 60 inches in depth of sand of an effective size of 0.29 millimeter. The history of this filter up to Dec. 31, 1894, has been published in previous reports of the Board. Its history during 1895 contains the following principal points:—

From Dec. 1, 1894, to April 30, 1895, the filter was not operated. On May 1, 1895, with a depth of sand equal to 52 inches, after having been filled slowly from below with city water, filtration of canal water was begun at a prescribed rate of 7,000,000 gallons per acre daily. A short trap attached to the outlet prevented air from entering at that point. Owing to low water in the canal the gate on the outlet remained closed and the surface of the sand covered with water on May 5, 18, June 8, July 6, 13, and August 3, for periods varying from seven to thirty-nine hours. In order to remove clogging, the surface was scraped as follows: May 25, 0.40 inch of sand was removed; June 12, 0.31 inch; June 29, 0.48 inch; June 22, 0.22 inch; July 5, 1.06 inches; July 16, 0.36 inch; July 22, 0.26 inch; July 26, 0.44 inch; July 31, 0.34 inch; on August 1, enough sand was removed to reduce the depth of filtering material to 36 inches; on August 21, 0.40 inch; on August 28, 0.45 inch. The surface was not raked after scraping and the filter was filled usually with canal water from above, but on July 31 city (filtered) water was applied below until the surface of the sand was covered with water before canal water was applied.

*Bacillus prodigiosus* mixture was applied to this filter from July 9 to 22 in the proportion of 1 part solution in 170,000 parts of applied water. A record of the daily (excepting Sundays and certain other days) bacterial analyses of the effluent will be found in the following table:—

*Average Daily Number of Bacteria per Cubic Centimeter in Effluent of Filter  
No. 44, 1895.*

*Filter No. 45.*

This intermittent filter was started July 10, 1893, and contained 60 inches in depth of sand of an effective size of 0.23 millimeter. The history of this filter up to Dec. 31, 1894, has been published in previous reports of the Board. Its history during 1895 contains the following principal points:—

From Dec. 1, 1894, to April 30, 1895, the filter was not in operation. On May 1, 1895, with a depth of sand of 57 inches, after having been filled with city (filtered) water from below, the filter began to filter canal water at a prescribed rate of 5,000,000 gallons per acre daily. The period of intermittent operation was arranged in such a manner that the surface of the sand remained uncovered for two hours during the day, excepting on Sundays, when the filter ran continuously. A trap attached to the outlet prevented air from entering at that point. On May 25 a stoppage in the pipe cut off the applied water, and the surface remained uncovered for twenty-seven hours. Owing to low water in the canal the gate on the outlet remained closed and the surface of the sand covered with water on the following dates: May 5, June 8, July 6, 13, August 3, September 22 and 28, for periods varying from twenty-four to thirty-nine hours. In order to remove clogging the surface was scraped as follows: on May 29, 0.36 inch of sand was removed; June 14, 0.42 inch; June 25, 0.52 inch; July 5, 0.46 inch; July 22, 0.36 inch; July 29, 0.32 inch; on August 1, enough sand was removed to reduce the filtering material to 36 inches; August 30, 0.60 inch; September 20, 0.60 inch; October 15, 0.54 inch; November 1, 0.42 inch; November 19, 0.44 inch. The surface was not raked after scraping, and the filter was filled immediately with canal water from above.

The rate of filtration was fluctuated as follows: on October 4 the gate on the outlet was closed for one minute and then opened to the usual point; on November 12 the gate was opened a little wider than usual, and on November 22 the gate was thrown wide open for one minute and then closed to the usual point.

*Bacillus prodigiosus* mixture was applied to this filter from June 22 until November 22, in the ratio of 1 part to 170,000 parts of applied canal water. The following table contains a record of the daily (excepting Sundays and on certain other occasions) bacterial analyses of the effluent from this filter:—

*Average Daily Number of Bacteria per Cubic Centimeter in Effluent of Filter No. 45, 1895.*

*Filter No. 46.*

This continuous filter was started on Aug. 21, 1893, and contained 12 inches in depth of sand of an effective size of 0.29 millimeter. The history of the filter up to Dec. 31, 1894, has been published in previous reports of the Board. Its history during 1895 contains the following principal points:—

From Dec. 1, 1894, to April 30, 1895, the filter was not operated. On May 1, with a depth of sand of 10 inches, after having been filled slowly with city water from below, canal water was applied continuously at a prescribed rate of 5,000,000 gallons per acre daily. A trap attached to the outlet prevented air from entering at that point. Owing to low water in the canal the gates on the outlet remained closed and the surface of the sand covered with water on the following dates: June 8, July 6, 13, and August 3, for periods varying from thirty-three to thirty-nine hours. In order to remove clogging the surface was scraped as follows: on May 23, 0.57 inch of sand was removed; on June 4, 0.48 inch; on June 17, 0.32 inch; on June 22, 0.38 inch; on June 26, 0.43 inch; on July 2, 0.39 inch; on July 10, 0.35 inch; on July 20, 0.47 inch; on July 26, 0.35 inch; on July 31, 0.35 inch; on August 6, 0.35 inch; on August 13, 0.41 inch; on August 21, 0.38 inch; on August 29, 0.49 inch. After scraping, the filter was not raked, but canal water was applied immediately from above. A record of daily (excepting Sundays and on a few other occasions) bacteria analyses will be found in the following table:—

*Filter No. 47.*

This intermittent filter was started Sept. 9, 1893, and contained 60 inches in depth of sand of an effective size of 0.29 millimeter. Its history up to Dec. 31, 1894, has been published in previous reports of the Board. The history of the filter during 1895 contains the following principal points:—

From Dec. 1, 1894, to April 30, 1895, the filter was not in operation. On May 1, 1895, with a depth of sand of 51 inches, after having been filled slowly from below with city water, filtration of canal water was begun at a rate of 7,000,000 gallons per acre daily. The period of intermittent operation was arranged in such a manner that the surface remained uncovered for two hours during the day. A trap attached to the outlet of the filter prevented air from entering at that point. Owing to low water in the canal the gate on the outlet remained closed on the following dates: June 8, July 6, 13 and August 3, for periods varying from thirty-three to thirty-nine hours. In order to remove clogging the surface was scraped as follows: on May 17, 0.30 inch of sand was removed; on May 30, 0.45 inch; June 8, 0.35 inch; June 19, 0.30 inch; June 21, 0.44 inch; June 25, 0.37 inch; on June 29, 0.32 inch; July 2, 0.31 inch; July 6, 0.30 inch; July 11, 0.28 inch; July 17, 0.29 inch; July 24, 0.37 inch; July 27, 0.24 inch; on August 1 the filtering material was reduced to 36 inches in depth; August 16, 0.34 inch; August 27, 0.48 inch. After scraping, the surface was not raked, but canal water was applied immediately from above. On July 29 the filter

was filled with city water from below. A record of the daily (excepting Sundays and on certain other occasions) bacterial analyses will be found in the following table:—

*Filter No. 48.*

This continuous filter was started Sept. 9, 1893, and contained 60 inches in depth of sand of an effective size of 0.38 millimeter. The history of this filter up to Dec. 31, 1894, has been published in previous reports of the Board. Its history during 1895 contains the following principal points:—

From Dec. 1, 1894, to May 15, 1895, the filter was not in operation. On May 16, 1895, it was filled slowly with city water from below. On May 17, with a depth of sand equal to 51 inches, it began to filter city (filtered) water continuously at a rate of 5,000,000 gallons per acre daily. On June 17 the city water was shut off and canal water applied from that date until November 23, when the canal water was shut off and city (filtered) water again applied for one week. A trap attached to the outlet prevented air from entering the filter at that point. Owing to low water in the canal the gate on the outlet remained closed, and the surface of the sand covered with water on the following dates: June 8, July 6, 13, August 3, September 22 and 28, for periods varying from twenty-four to forty hours. In order to remove clogging the surface of the sand was scraped as follows: July 17, 0.57 inch of sand was removed; August 9, 0.38 inch; August 21, 0.40 inch; September 4, 0.45 inch; September 16, 0.39 inch; September 28, 0.40 inch; October 15, 0.44 inch; October 30, 0.68 inch; November 13, 0.37 inch; November 19, 0.26 inch. After scraping, the surface was not raked, and canal water was applied at the top immediately. November 13 the surface was dug over 6 inches deep, after scraping, and on November 19, city (filtered) water was applied slowly from below until the surface of the sand was covered with water.

The rate of filtration was fluctuated as follows : on September 14 the gate on the outlet was closed for one minute and then opened to the usual point ; on October 9 the gate was thrown wide open, and on October 16, 21, 26, the gate was opened a little wider than usual for one minute and then closed to the usual point.

In order to test the bacterial efficiency of the filter a solution seeded with *Bacillus prodigiosus* was mixed with the applied canal water in the ratio of 1 part to 170,000 parts, for ten hours a day, from June 10 to November 23. A record of the daily (excepting Sundays and on certain other occasions) bacterial analyses will be found in the following table :—

*Average Daily Number of Bacteria per Cubic Centimeter in Effluent of Filter No. 48, 1895.*

*Filter No. 49.*

This continuous filter was started Sept. 9, 1893, and contained 60 inches in depth of sand of an effective size of 0.38 millimeter. The history of the filter up to Dec. 31, 1894, has been published in previous reports of the Board. Its history during 1895 contains the following principal points:—

From Dec. 1, 1894, to May 15, 1895, the filter was not in operation. On May 16, 1895, it was filled slowly from below with city (filtered) water and allowed to stand over night. On May 17, with 56 inches in depth of sand it began to filter city (filtered) water continuously at a rate of 10,000,000 gallons per acre daily. June 17 the city water was shut off and canal water applied regularly until November 23, when the city water was turned on again for one week. A short trap attached to the outlet prevented air from entering at this point. The surface of the sand became uncovered on May 21, therefore the filter was filled from above, the gates closed and the filter allowed to rest for fourteen hours. On account of low water in the canal the gate on the outlet remained closed and the surface of the sand covered with water on the following dates: June 8, July 6, 13, August 3, September 22 and 28, for periods varying from twenty-four to forty hours. In order to remove clogging the surface of the filter was scraped as follows: on June 30, 0.45 inch of sand was removed; July 13, 0.52 inch; July 22, 0.44 inch; July 27, 0.38 inch; July 30, 0.41 inch; August 3, 0.47 inch; August 9, 0.54 inch; August 14, 0.39 inch; August 21, 0.34 inch; August 23, 0.37 inch; September 5, 0.44 inch; September 9, 0.47 inch; September 12, 0.68 inch; September

25, 0.42 inch; September 30, 0.32 inch; October 9, 0.48 inch; October 11, 0.20 inch; October 15, 0.27 inch; October 24, 0.58 inch; October 30, 0.68 inch; November 2, 0.63 inch; November 5, 0.68 inch; November 9, 0.24 inch; and November 19, 0.30 inch. After scraping, the filter was not raked, and canal water was applied above immediately. On November 9 the surface was dug over 6 inches, and on November 18, after filling from above with canal water, the filter stood for an hour, after scraping, before being put into operation.

The rate of filtration was fluctuated as follows: on September 14 the gate was opened a little wider than usual, and on October 21 the gate was thrown wide open for one minute and then closed to the usual point. A solution seeded with *B. prodigiosus* was applied, as in the case of Filter No. 48.

A record of the daily (excepting Sundays and on certain other occasions) bacterial analyses will be found in the following table:—

*Average Daily Number of Bacteria per Cubic Centimeter in Effluent of Filter No. 49, 1895.*

*Filter No. 50.*

This continuous filter was started July 23, 1894, and contained 60 inches in depth of sand of an effective size of 0.48 millimeter. The history of the filter up to Dec. 31, 1894, has been published in previous reports of the Board. Its history during 1895 contains the following principal points:—

From Dec. 1, 1894, to April 30, 1895, the filter was not in operation. On May 1, 1895, with a depth of 58 inches, after having been filled slowly from below with city water, this filter began to filter canal water continuously at a prescribed rate of 5,000,000 gallons per acre daily. A trap attached to the outlet of the filter prevented air from entering at that point. Owing to a stoppage in the feed-pipe on May 25, the surface of the sand became uncovered, and the filter was not in operation for twenty-six hours. On account of low water in the canal the gate on the outlet was closed, though the surface remained covered with water, on the following dates: June 8, July 6, 13, August 3, September 22 and 28, for periods varying from twenty-four to thirty-nine hours. In order to remove clogging the surface of the sand was scraped as follows: on June 18, 0.41 inch of sand was removed; on July 18, 0.47 inch; July 27, 0.47 inch; August 21, 0.63 inch; on August 31 enough sand was removed to reduce the depth of filtering material to 36 inches; October 15, 0.42 inch; November 7, 0.70 inch. After scraping, the filter was not raked, and canal water was applied above, except on October 15, when the filter was filled slowly with city water from

below. On October 7 the rate of filtration was fluctuated by closing the gate on the outlet for one minute and then opening the gate abruptly to the usual point. A record of the daily (excepting Sundays and on certain other occasions) bacterial analyses will be found in the following table:—

*Average Daily Number of Bacteria per Cubic Centimeter in Effluent of Filter No. 50, 1895.*

*Filter No. 62.*

This continuous filter was started Sept. 2, 1895, and contained 48 inches in depth of sand of an effective size of 0.40 millimeter. The history of this filter during 1895 contains the following principal points:—

The sand for this filter was obtained from the beach at Plum Island on the sea coast 20 miles from Lawrence. Canal water was applied slowly from above until it covered the surface of the sand. The filter then stood full of water for forty-eight hours, and started, on September 2, to filter canal water continuously at a prescribed rate of 5,000,000 gallons per acre daily. A trap attached to the outlet prevented air from entering at this point. Owing to low water in the canal the gate on the outlet remained closed and the surface of the sand covered with water on September 22 and 28 for twenty-four and thirty-three hours, respectively. In order to remove clogging the surface of the sand was scraped as follows: on October 2, 0.30 inch of sand was removed; October 24, 0.50 inch; November 9, 0.47 inch; and on November 19, 0.41 inch. After scraping, the surface was not raked. On October 2 and 24 the filter was filled slowly from below with city water, but on November 9 and 19 canal water was applied above, immediately after scraping.

On September 19 the rate was fluctuated by closing the valve on the outlet for one minute and then opening the valve suddenly to the usual point. On October 19 the rate was fluctuated by throw-

ing the valve wide open for a minute and then closing it to the usual point.

A solution seeded with *B. prodigiosus* was mixed with the applied canal water in the ratio of 1 part to 170,000, for ten hours daily, from September 26 to November 23.

When the filter went out of operation on Nov. 23, 1895, the valve was thrown wide open and the sand allowed to drain.

A record of the daily (excepting Sundays and on some other occasions) bacterial analyses will be found in the following table:—

*Average Daily Number of Bacteria per Cubic Centimeter in Effluent of Filter No. 62, 1895.*

*Filter No. 63.*

This continuous filter was started Sept. 2, 1895, and contained 24 inches in depth of sand of an effective size of 0.16 millimeter. The history of its construction and operation during 1895 is as follows: —

After removing the sand from Filter No. 38, without disturbing the under-drains, 2 feet of Berkshire sand — a white, sharp, pure quartz sand, such as is used in the manufacture of glass — was put into the filter dry. Canal water was then applied from above until the surface of the sand was covered. Having stood full of water for forty-six hours the filter began, on September 2, to filter canal water continuously at a prescribed rate of 5,000,000 gallons per acre daily. A trap attached to the outlet prevented air from entering at that point. Owing to low water in the canal the gate on the outlet remained closed, and the surface of the sand covered with water on September 22 and 28, for periods varying from twenty-four to thirty-three hours. On September 21 the filter drained until the surface of the sand almost became uncovered. In order to remove clogging the surface of the sand was scraped as follows: on September 12, 0.39 inch of sand was removed; on September 19, 0.32 inch; October 2, 0.28 inch; October 9, 0.26 inch; October 16, 0.36 inch; October 19, 0.34 inch; October 28, 0.33 inch; November 2, 0.28 inch; November 7, 0.40 inch; November 16, 0.49 inch; November 19, 0.34 inch. After scraping, the filter was not raked, and canal water was applied above immediately, except on October 9, when the filter was filled slowly from below with city water. On November 9 the rate was fluctuated by opening the faucet for one minute, so that the normal rate was doubled.

A solution seeded with *B. prodigiosus* was mixed with the applied canal water in the proportion of 1 part to 170,000, for 10 hours a day (excepting Sundays and on some other occasions), from September 26 to November 23. On the latter date the filter went out of operation for the year. It was allowed to drain and the outlet remained open during the winter.

A record of the daily (excepting on Sundays and on certain other occasions) bacterial analyses will be found in the following table:—

*Average Daily Number of Bacteria per Cubic Centimeter in Effluent of Filter No. 63, 1895.*

*Filter No. 64.*

This continuous filter was started Sept. 2, 1895, and contained 12 inches in depth of sand of an effective size of 0.16 millimeter. The method of construction and the history of this filter during 1895 is as follows:—

After removing the sand from Filter No. 46, without disturbing the under-drains, 1 foot of Berkshire sand—similar to that already described under Filter No. 63—was put into the filter dry. Canal water was then applied from above until the surface of the sand was covered. Having stood full of water for forty-six hours, the filter began to filter canal water continuously, on September 2, at a prescribed rate of 5,000,000 gallons per acre daily. A trap attached to the outlet prevented air from entering at that point. Owing to low water in the canal the filter remained closed and the surface of the sand covered with water, on the following dates: September 22 for twenty-four hours and September 28 for thirty-three hours. In order to remove clogging the surface of the sand was scraped as follows: on September 10, 0.26 inch of sand was removed; September 16, 0.30 inch; September 21, 0.28 inch; September 28, 0.35 inch; October 5, 0.27 inch; October 11, 0.26 inch; October 26, 0.32 inch; October 17, 0.42 inch; October 21, 0.28 inch; October 26, 0.26 inch; November 1, 0.34 inch; November 5, 0.31 inch; November 9, 0.35 inch; November 15, 0.34 inch; and November 19, 0.34 inch. After scraping, the surface was not raked but canal water applied from above immediately.

On October 29 the rate was fluctuated by increasing it for one minute from 5,000,000 to 7,500,000 gallons per acre daily. On November 23 the filter was shut off for the winter, and the gate on the outlet left open to allow the filter to drain.

A solution seeded with *Bacillus prodigiosus* was mixed with the applied canal water in the ratio of 1 part to 170,000 parts, for ten hours a day (excepting Sundays and on some other occasions), from September 26 to November 23.

A record of the daily bacterial analyses (excepting on Sundays and on certain other days) will be found in the following table:—

*Average Daily Number of Bacteria per Cubic Centimeter in Effluent of Filter No. 64, 1895.*

## LAWRENCE CITY FILTER.

The filter of the water supply system of the city of Lawrence is 2.5 acres in area, was first put in operation Sept. 20, 1893, and its construction and action was described in the report of the State Board of Health for that year. From the date of starting this filter up to the present time it has been in continuous use, and not once has the unfiltered river water entered the reservoir or the service pipes of the city water supply.

The average bacterial efficiency of the filter for the entire year has always been about 99 per cent., but varies with different seasons, being considerably greater in summer than in winter. The most important reason for the lower bacterial efficiency in winter is that, contrary to the advice of the designer, the filter remains uncovered and unprotected from the severe cold of the winters of the climate of Lawrence. In consequence of this a thick coating of ice forms upon the filter, and, to enable the surface of the filter to be cleaned of clogged and dirty sand, and thus kept in operation, this layer of ice, sometimes approximating 2 feet in thickness, has to be removed. Its removal is slowly accomplished by the city laborers and the surface of the filter very much disturbed during the process. With the force employed the removal of the main body of the ice is so slowly accomplished that in order to get a sufficient daily volume of water through the filter, it is necessary to frequently stop removing the thick ice and remove the newly formed ice and scrape the beds just previously scraped. With these conditions abnormal and unnecessary results are obtained. That is to say, as a result of this management, a small portion of the filter is, for weeks at a time, filtering a very large proportion of the water pumped. The surface of the filter is divided by drains and elevations of its surface into thirty-three sections or beds, and between December 11 and April 10 the first two beds (beginning at the end of the filter nearest the pumping house) were scraped and raked eight times, the next eighteen beds five and one-half times and the remaining thirteen beds two and one-half times, and these last were not scraped at all during January and February.

This method of operation is unfavorable to obtaining efficient filtration, and if the filter remains uncovered it will be necessary to remove the ice with sufficient rapidity to clean all of the beds monthly and to avoid repeated scraping of the same beds and the

consequent filtration of a large part of the water through a small area of the filter at a very high rate.

An experiment to illustrate the effect of this treatment upon bacterial efficiency was made with Filter No. 3 B at the station. About one-quarter of the surface of this filter was scraped and then disturbed to the depth of several inches and the filter started at its rate of filtration of 5,000,000 gallons per acre daily. The average number of bacteria per cubic centimeter in the effluent of this filter before this treatment was 7 per cubic centimeter; following the treatment the number quickly increased to a maximum of 1,897 per cubic centimeter and not for several days did the bacterial efficiency of the filter return to the normal. This is parallel to the treatment of the Lawrence city filter in the winter months, which results in giving at times the high numbers of bacteria in its effluent presented in the tables on page 573, and those in charge have been repeatedly advised against this unfavorable method of operation.

Beginning Nov. 15, 1895, a daily bacterial analysis was made of the river water before and after its passage through the filter, and as it flowed from taps at the city hall and experiment station. This daily bacterial examination was continued until May, and the results are presented beyond. The hygienic efficiency of the filter is shown by a table on page 7.

During the winter months the filter is at times operated continuously.

#### *Cost of Operation of the Filter.*

During 1895, 1,096,000,000 gallons of water passed through the city filter, and upon page 7 of the report of the Lawrence water board for the year 1895 it is stated that the cost of maintenance of the filter for the year was \$11,038. Exclusive of amounts not properly chargeable to filter maintenance, such as grading, paving, care of lawns and improvements about the pumping station and filter beds, the total expense for maintenance was \$7,400, or \$6.75 per million gallons of water filtered. The itemized figures for the year kindly furnished by Mr. Salisbury, the superintendent of the Lawrence water department, are as follows: for scraping the filter and replacing sand, \$3,477; for removing ice, \$2,903; for washing 1,500 cubic yards of sand, \$1,020. For scraping and replacing sand only, the cost was \$3.10 per million gallons filtered. All laborers upon this work are paid \$2 per day.

# METHODS EMPLOYED AT THE LAWRENCE EXPERIMENT STATION FOR THE QUANTITATIVE DETERMINATION OF BACTERIA IN SEWAGE AND WATERS.

---

By GEORGE W. FULLER and WILLIAM R. COPELAND.

---

In this paper it is proposed to record briefly the methods which have been employed recently in the determination of the number of bacteria in sewage and waters. It is also desired to point out certain modifications which have been made since the methods were originally described in the report of the State Board of Health upon the purification of sewage and water (1), and further, to present the evidence on which the more important changes were based.

The principal topics treated in this paper are noted in the following outline : —

1. Collection and storage of samples.
2. Preparation of culture media.
3. Sterilization and storage of culture media.
4. Technique of plating.
5. Technique of counting colonies of bacteria on plates.
6. Effect of length of period of cultivation and of temperature at which cultivation takes place.
7. Comparison of the relative values of gelatine and glycerine agar for quantitative bacterial work.
8. Roll cultures in four liter bottles.

## *Collection and Storage of Samples.*

The samples of sewage, etc., for bacterial analysis are collected in mushroom ground-glass stoppered bottles of a capacity of about one ounce. Special care has been taken to procure a glass stopper with a mushroom top rising about half an inch from the top of the bottle. This form of stopper protects the mouth of the bottle from becoming contaminated by the fingers in removing the sterilized

bottle from its tin case. The bottles (especially new ones) are soaked for several hours in a solution of potassium permanganate and caustic soda. In fact, all glassware is treated with this solution before it is sterilized in order to remove all trace of organic matter; otherwise, organic matter contained in the bottle might serve as a food material for the bacteria present in the water to be analyzed and so allow them to multiply.

After treatment with permanganate, the bottles are rinsed in a dilute solution of sulphuric and oxalic acids. These acids remove the excess of permanganate and neutralize the free alkali. It is necessary to use much care in washing the bottles with water in order to remove all acid and to obtain as a result a sample bottle which is chemically clean. After cleaning and drying, the bottles, carefully stoppered, are placed in covered tin boxes made to fit the bottles approximately. The encased bottles and other glassware are then sterilized in an oven over a gas stove at a temperature of 160 degrees C. for an hour and a half.

When samples of sewage or water have been collected in such bottles they are placed in the ice compartment of a refrigerator, where, at a temperature of from 5 to 10 degrees C., they may be left for several hours without change. It should be noted here that samples collected out of town are not generally taken to the laboratory before plating, but are plated on the spot by the collector.

### *Preparation of Culture Media.*

Until July, 1894, nutrient gelatine was employed as the regular culture medium for quantitative bacterial work. Since July, 1894, nutrient glycerine agar has been used instead of nutrient gelatine. In addition to gelatine and glycerine agar, a solution composed of one-tenth of one per cent. of peptone and two-tenths of one per cent. of powdered glucose in sterilized tap water has been used to obtain a pure culture of *Bacillus prodigiosus*. A measured quantity of this solution, seeded with this specific germ, has been applied from time to time to the several experimental water filters, as described on page 598.

The ingredients used have been of as high a grade as could be obtained from the best dealers. Meat infusions were made, prior to July, 1892, by allowing one pound of finely chopped lean meat to digest in one liter of cold water for about twenty hours. The

infusions were filtered while cold. This treatment removed almost all of the fat globules, while the filtrate contained the various other substances extracted from the meat. From July, 1892, to January, 1894, meat infusions were made by allowing one pound (about four hundred and fifty grams) of finely chopped lean meat to digest in one liter of warm tap water for two hours; they were then heated for thirty minutes in a bath of boiling water, boiled for ten minutes over a free flame, and filtered, while hot, to remove the particles of meat, fat and coagulated albumen. In January, 1894, it was decided to return to the original method of digesting the meat in cold water for the reasons which will appear beyond.

Until Dec. 15, 1894, Witte's peptone was used. Since Dec. 15, 1894, Merck's "Peptonum Siccum" has been used instead of Witte's. The leaf gelatine used is made by Comte Fils, and labelled "Best French Brand." Agar free from acid has been used, and the glycerine has been twice distilled. The powdered glucose used is a high-grade commercial product. Common table salt has been used in the proportion described in the original formula of Koch, apparently with the view to aid in dissolving ingredients of nutrient culture media.

Nutrient gelatine is prepared by adding to one liter of meat infusion one per cent. by weight of peptone, one-half of one per cent. of salt and ten per cent. of gelatine. After weighing the dish containing these substances it is placed in a bath of boiling water and stirred constantly for ten minutes. By this time the gelatine and peptone are dissolved, and, after replacing the water which has evaporated as shown by loss in weight, five cubic centimeters of the solution are placed in a porcelain evaporating dish containing fifty cubic centimeters of distilled water. It has been the custom to boil this solution for three minutes over a free flame in order to expel carbon dioxide and free ammonia which may have been present. These gases, otherwise, would interfere with the accuracy of the titration with phenolphthalein, which is used as an indicator in the determination of the acidity of the solution. After boiling for three minutes, one cubic centimeter of phenolphthalein (five grams of powder in one liter of fifty per cent. alcohol) is added, and while the solution is still hot, enough twentieth normal caustic soda added from a burette to produce a slight pink color. By this method it is possible to determine accurately the acidity of the solution (2).

Experience has shown that the acidity of gelatine solutions is so

great at this point that it is necessary to add from fifty-five to seventy cubic centimeters of normal caustic soda solution to one liter of gelatine in order to neutralize the acid present, when phenolphthalein is used as an indicator. It should be noted here that the scale adopted at the Lawrence Experiment Station is based on the number of cubic centimeters of normal caustic soda which must be added to one liter of solution to produce a neutral reaction with phenolphthalein.

The amount of acid found in the solution varies with the composition of the meat infusion, peptone and gelatine employed (2).

When the degree of acidity has been determined enough normal caustic soda is added to the solution to reduce the acidity of the entire volume to a point which is slightly alkaline to blue litmus paper if Schultz's method is to be employed in the preparation of gelatine, or slightly alkaline to phenolphthalein if Timpe's method is followed. These two methods of procedure are described beyond.

The advantage of allowing the meat to remain for twenty hours in water in an ice-chest, and of filtering the meat infusion while cold, now becomes apparent because the albumens left in the meat infusion serve as a coagulant in place of egg albumen, which, following the practice described in text books, is customarily added at this time to replace the albumens precipitated and removed from the solution by filtration if the infusion is extracted with boiling water.

When the alkali has been mixed thoroughly with the solution the dish is placed in a bath of boiling water for twenty minutes. After this the dish is removed from the water bath and set over a free flame for five minutes with constant stirring; by this treatment the solution is brought to a boil for two minutes, to aid in making it clear. After adding enough boiling water to replace the water which has evaporated, five cubic centimeters of the solution are again titrated as described above. The degree of reaction changes slightly during the process of heating. Owing to changes in some of the ingredients the solution becomes a little more acid (from three to five cubic centimeters of normal acid per one liter). The next step in the process is to filter the solution rapidly through coarse flannel and absorbent cotton. To the filtrate it is necessary to add enough normal acid or alkali to produce the required degree of reaction. The gelatine is then placed in sterilized test-tubes (five cubic centimeters in each tube) and the tubes plunged at once

into cold water until the gelatine has solidified. These tubes are then sterilized in an Arnold steam sterilizer for thirty minutes on each of three consecutive days, or in an autoclave at a pressure of one atmosphere for from five to seven minutes.

Nutrient agar is prepared by adding to one liter of meat infusion, peptone and salt as in the preparation of gelatine, and one and three-tenths per cent. by weight of finely chopped agar. The remaining steps in its preparation are similar to those already described for gelatine, except that it is the custom to boil agar slowly for one hour over a free flame. To assist the process of dissolving the agar, five hundred cubic centimeters of water are added to the original volume of one liter before heat is applied.

Agar itself has been found to be neutral to phenolphthalein, therefore, the reaction of the solution is much lower at this point than a solution of gelatine would have been. The total acidity of the solution at this point ranges from thirty-five to forty-five cubic centimeters of normal acid per liter.

After titration and addition of normal alkali the agar is placed over a free flame and boiled slowly for two hours. In order to keep conditions of temperature and volume as nearly constant as possible during this process, boiling water is added from time to time to replace the water which has evaporated. When the agar has been heated for two hours and has been restored to its original volume it is filtered and titrated. The reaction of the medium changes very little during this process of heating. To the filtrate six per cent. by weight of twice-distilled glycerine is added, the solution titrated and enough normal acid or alkali put in to produce the required reaction. The solution is then tubed and placed in cold water. As agar does not lose its power to solidify even though heated for a long period of time, it has been the custom to sterilize it in the Arnold steam sterilizer for one hour on each of three consecutive days. Since June, 1895, it has been the custom to sterilize it in an autoclave for fifteen minutes at a pressure of one atmosphere.

As noted above, both Witte's and Merck's peptones have been used in these investigations, and Merck's has been employed during the present year. Experiments have shown that the composition of peptones influences somewhat the bacterial results, as has been described in an article published elsewhere (2) (8).

The present supply of Merck's peptone is found to be very satisfactory.

Reference has already been made to Schultz's (3) and Timpe's methods of alkalization. Schultz's method affords a more accurate means than the method originally described by Koch of carrying out the general procedure, and has been followed almost from the outset in the preparation of nutrient culture media. In brief, this method consists of adding enough normal alkali to an acid solution of a nutrient medium to reduce the acidity before heating to the degree which it is desired to maintain in the nutrient medium for plating. Timpe's (4) method consists of adding enough normal alkali to reduce the acidity before heating to the neutral point (phenolphthalein being used as an indicator) and the addition after heating of enough normal acid or alkali to the filtrate to produce the desired degree of reaction.

Until the middle of the year 1891 the method ordinarily described in text-books was followed. From July 1, 1891, to Jan. 1, 1895, Schultz's method was used at this laboratory, but it was then decided to change to Timpe's method because it appeared that by making the medium neutral each time before cooking, the chemical changes which take place proceed always under conditions which are more nearly parallel. Experience at this laboratory indicates that the final degree of reaction may be obtained more easily and more accurately by adding a definite number of cubic centimeters of normal acid or alkali to a liter of neutral culture medium, as described in Timpe's method, than by reducing the acidity to the required degree after the first heating, according to Schultz's method, because in the latter case the reaction seems to change during the subsequent process of preparation.

In this connection it should be noted that the degree of reaction has a decided effect on the development of the number of colonies on plates. Mr. J. J. Mackensie finds that (5) for Toronto tap water a nutrient gelatine neutral to phenolphthalein is most favorable. Dr. Johnston (6) found that nutrient gelatine with reaction which corresponds to No. 20 on this scale was favorable. This matter has been discussed in detail in an article published elsewhere, but in order to bring out the great importance of this subject the following table is again presented (2) :—

*Table showing a Comparison of Representative Results of the Quantitative Determination of Bacteria in Lawrence Sewage, Merrimack River Water and Lawrence City (Filtered) Water on Gelatine of Different Degrees of Reaction, but with other Conditions the same.*

| REACTION.*     | LAWRENCE SEWAGE.               |                                                                     | MERRIMACK RIVER WATER.         |                                                                     | LAWRENCE CITY WATER (FILTERED). |                                                                     |

\* Numbers refer to cubic centimeters of normal acid or alkali which must be added to a liter of nutrient medium in order to make it neutral to phenolphthalein. Minus (-) means an alkaline solution.

Following the custom practised in this laboratory the reaction of a solution which contains twenty cubic centimeters of normal acid in one liter is known as reaction No. 20. In connection with the preceding table it should be noted that reactions Nos. 18 to 20 were used in the laboratory from 1891 to 1895. The exact degree of reaction was determined at that time by titrating one cubic centimeter of the solution in five cubic centimeters of water. Since January, 1895, reactions Nos. 15 to 18 have been used; and the reaction has been determined by titrating five cubic centimeters of the solution in fifty of water, as already described.

As a result of these experiments it may be said that reactions Nos. 13 to 20 have been found to produce the development of the maximum number of bacteria.

The evidence at hand shows that the degree of reaction which is most favorable for bacterial growth varies somewhat with different

species of bacteria, with bacteria of different degrees of vitality but of the same species (9), and perhaps with the seasons of the year. A factor which should not be neglected is the variable amount of muscle sugar present in different meat infusions, as first pointed out by Dr. Theobald Smith (7). In view of these facts, therefore, reaction No. 18 cannot be said to be the optimum under all conditions, though it seems to come nearest to the optimum reaction so far as Lawrence conditions are concerned. The need and value of a uniform standard degree of reaction is insisted upon, however, for the sake of getting comparable results.

### *Sterilization and Storage of Culture Media.*

Gelatine has been sterilized for thirty minutes on each of three successive days in an Arnold steam sterilizer. It has often been noted, however, that gelatine plates would not solidify, especially in summer weather, and showed evident signs of contamination when sterilized in this manner. To obtain nutrient media which should be sterile every time and to avoid delay caused by heating on three days in succession, an autoclave was obtained in June, 1895. It has been necessary, at the station, to generate steam within the autoclave itself, and this extra heating tends to destroy the power of gelatine to solidify. Agar, and water for purposes of dilution, can be sterilized satisfactorily, however, and at the present time they are always sterilized in this manner.

In order to keep media in good condition a lot of two liters is made up at least once in two weeks, tubed and placed in the ice-chest. To make certain that the media are sterile they are heated for ten minutes in boiling water just before use for plating.

### *Technique of Plating.*

The technique of plating as applied to the bacterial analysis of water consists of mixing a measured amount of the samples of water with a certain amount of gelatinous nutrient medium, with proper precautions, in a Petri double dish, well known to bacteriologists. The method pursued in plating is as follows; after shaking thoroughly the glass bottle (described on page 585) containing the sample of water to be analyzed, one cubic centimeter is drawn out in a pipette graduated to discharge this quantity of water. This measured amount is discharged into a tube of melted nutrient medium (gelatine or agar), and after it has been thoroughly mixed with the food material the contents of the tube are poured into a sterile Petri

dish. As the solution enters the dish it is spread uniformly over the surface and allowed to solidify.

The previous shaking and mixing in the tube divides the bacteria from one another, and, as they lie scattered in the film over the surface of the plate, they are kept separate by the gelatinization of the medium. Under these favorable conditions each cell multiplies by fission and forms an independent colony.

*Technique of Counting Colonies of Bacteria on Plates.*

Since each bacterium is supposed to be in isolation, and in a position where it may multiply by cell division until a colony is formed, the actual number of individual bacteria which existed in one cubic centimeter of the original sample of water may be determined by counting these colonies. To facilitate the process of counting it is necessary to use special care in spreading the liquid medium in order to obtain a film as nearly uniform in thickness as possible over the whole surface of the plate. When so prepared it is possible to count accurately each colony on a plate containing eight hundred colonies, by the aid of a hand lens and a glass plate ruled with two sets of lines, forming squares one square centimeter in area (Wolffhügel's apparatus).

As the number of colonies increases to three thousand, other methods are employed, such as counting a diametrical section of the plate one centimeter in width. If the colonies on a plate amount to ten thousand or more it is customary to count only those bacteria which lie in three or more areas one centimeter square; these areas must be chosen with care so as to represent an average of the thick, medium and thin portions of the plate. As errors may easily creep in by counting areas which are not average examples of such portions of a plate, it is necessary that much care be taken to select representative areas.

It is essential that the temperature of the melted culture medium should be kept below 39° C. in order to prevent bacteria in the vegetative state from being killed by the heat of the solution. For the purpose of securing a uniform and satisfactory temperature when working with agar it is the custom to have the melted agar kept liquid for one hour before plating, in a water bath maintained at a temperature of 39° C. by an automatic regulator. On the other hand, the temperature of the melted tubes of culture media should not be allowed to become so low that the medium can-

not be poured from the tube readily. At best about five per cent. of the contents remain in the tube after pouring. As long as this percentage is kept constant the results are strictly comparable, although they do not comprise the entire contents of the cubic centimeter of water drawn from the sample for plating.

As Lawrence sewage often contains more than two million bacteria per cubic centimeter, in order to facilitate the estimation of the number of colonies, it is customary to reduce the number which otherwise would appear on a plate by mixing one cubic centimeter of the sample in a flask containing five hundred cubic centimeters of sterilized tap water; the flask is then well shaken, one cubic centimeter taken out and plated in the usual manner. Other samples of water, which contain five thousand or more bacteria in a cubic centimeter, are diluted in the ratio of one to one hundred by a similar process.

When the medium has become solid the plate is placed in a 20° C. thermostat to allow the colonies of bacteria to develop. Agar plates are inverted, to prevent the water of condensation from running over the surface of the medium, otherwise colonies of bacteria which lie on the surface would spread, together with this water, over the surface of the plate.

Agar plates stand in the thermostat for four days; but as certain bacteria peptonise or liquefy gelatine it is necessary to remove some gelatine plates to an ice-chest after forty-eight or sixty hours' growth. The cold temperature checks to a considerable degree the development of liquefying colonies but allows time for the further development of bacteria, which grow slowly.

Owing to the obliteration of small colonies, either by a thick film of bacteria which sometimes spreads over the surface of the medium or by liquefaction of the gelatine, it is possible that error may be introduced in the calculation of the number of colonies on a plate. It is necessary, therefore, to examine frequently and perhaps to count plates which contain such colonies before the normal time for development has expired.

*Effect of Length of Period of Cultivation and of Temperature at which Cultivation takes Place.*

The length of time during which a plate is allowed to develop and the temperature of the chamber in which the plates stand produce a marked effect on the number of colonies which will develop.

*Table showing the Number of Colonies per Cubic Centimeter which had developed on a Plate at Different Periods of Growth.*

| City (filtered) water, . . . . . | 3                                 | 62      | 83      | 89      | 30     | 71      | 76      | 82      | 28     | 36      | 41      | 44      |

NOTE.—These numbers are averages, in each instance, of sixteen sets of determinations made on separate days in June and July, 1895; all of the plates comprising a set on any special day having been made from a single sample of canal or city water.

Experiments have been made to test the effect produced by allowing plates to develop for a longer period. The power which some bacteria possess to liquefy gelatine or to form an opaque growth over a considerable portion of agar often makes it impossible to keep plates more than four days. An increase has been noted, however, in several instances when plates were allowed to develop for ten days. As the work at Lawrence calls for many plates containing liquefying and spreading colonies it has been thought best to adopt a rule which should secure, for purposes of comparison, counts of plates under conditions as nearly parallel as possible. For this reason plates have always been counted on the fourth day. It sometimes happens, however, that plates which have been partially liquefied or contain spreading colonies present a smaller number of colonies on the fourth than on the third day. Under such conditions the highest number has been taken.

*Comparison of the Relative Value of Gelatine and Glycerine Agar for Quantitative Bacterial Work.*

Work at the Lawrence Experiment Station often has to deal with samples of sewage and water which contain large numbers of bacteria. Many of these bacteria liquefy gelatine plates. The nutrient gelatine itself has been found to melt if the plates are allowed to stand a short time on the laboratory table in hot weather, thereby causing the value of counts on gelatine plates to be much impaired. As the gelatine did not melt in cold weather it was possible to count the bacteria more accurately, and therefore determinations made at different seasons of the year were not as comparable as desired. Reference has already been made to the difficulty experienced in sterilizing gelatine.

Glycerine agar was found as a result of long experiment to be a medium which would give a maximum number of colonies at all seasons of the year, a medium in which sewage bacteria could grow rapidly without being able to liquefy it, and a medium which could be heated in our autoclave until sterile without losing its power of solidification. Moreover, it was found that, by careful observation of necessary precautions, agar would give results which compared favorably with gelatine and often gave better results than gelatine in summer. For these reasons it was decided to substitute glycerine agar for gelatine in a considerable portion of the work, while making frequent control cultures with ordinary nutrient gelatine.

| May, . . .     | 4,490,000 | 4,630,000       | 251                           | 269             | 5,200        | 5,500           | 34                                 | 34              |

NOTE.—The numbers given in this table are averages of numerous determinations. The plates were allowed to develop from three to four days. The low numbers given in certain instances for gelatine plates are due to liquefaction of the gelatine.

It was known that results were sometimes higher on gelatine than on glycerine agar, as indicated in this table, and that the development on the former medium is somewhat more rapid, but it was believed that glycerine agar under the actual conditions gave results which for all seasons of the year were more nearly comparable. Numerous comparative results have been obtained at frequent intervals, and the earlier data have been confirmed in a general way.

### *Roll Cultures in Four-liter Bottles.*

Reference has already been made to the use of peptone glucose solutions (one-tenth per cent. peptone and two-tenths per cent. of glucose in tap water) containing a pure culture of *Bacillus prodigiosus* for testing the efficiency of sand filters. A measured quantity of the solution containing large numbers of this germ is mixed with the water on the surface of the filter. The amount of solution applied varies with the area of the filter, rate of filtration and other conditions. As this bacillus has not been found to occur naturally in Lawrence waters it is used to test the power of filters to remove bacteria, because any *B. prodigiosus* cells which appear in the effluent must have passed through the sand in the filter. Further, it has been learned by numerous experiments that this germ does not grow within filters, and in this respect it differs from many common water bacteria and resembles the germ of typhoid fever. Still another advantage in the use of *B. prodigiosus* lies in the ease with which it may be identified. By the determination of the exact number of cells of *Bacillus prodigiosus* applied and the number which appear in the effluent it is possible to obtain valuable tests upon the efficiency of the filter both quantitatively and qualitatively.

The effluent of some of the Lawrence experimental water filters amounts to twenty thousand gallons of water in a day. It is impossible to examine all of such effluents and yet it is desirable to test them as thoroughly as possible. This is usually done by taking samples at frequent intervals during the day. But in the application of *B. typhosus* and *B. prodigiosus* to many of the filters it has been found that a large number of the plates seeded with one cubic centimeter of effluent do not contain any of those specific germs which have been added to the water as it enters the filter. In other words, there are fewer than one bacteria of this kind per cubic centimeter. Circumstances have been such that it has been desirable to study more thoroughly the presence of the specific germ in the effluent, and to learn, for

instance, whether the average number would be 0.1 or 0.01 per cubic centimeter. To accomplish this purpose fifty cubic centimeters of effluent are mixed with one hundred cubic centimeters of gelatine (twenty per cent. of gelatine in one liter) in a four-liter bottle. By rolling the bottle as it lies on its side on a cake of ice the fifty cubic centimeters mixed together with the gelatine are distributed over the large inner surface of the bottle.

The advantage of using this method to test waters for a certain species is great when the total number of bacteria is small, because it is possible to analyze a large number of cubic centimeters of effluent at one time and yet have the single colonies isolated.

# SEWAGE PURIFICATION

OF

CITIES AND TOWNS IN MASSACHUSETTS.

---

---

## SEWAGE PURIFICATION OF CITIES AND TOWNS IN MASSACHUSETTS.

---

In order to learn the results obtained by the systems of sewage disposal in the cities and towns in Massachusetts which have adopted a method of sewage purification, the State Board of Health since 1892 has caused chemical analyses to be made of sewage and effluent from many of the systems now in operation.

The results for the year 1892 were printed in connection with a paper upon the "Sewage disposal of cities and towns in Massachusetts by intermittent filtration," in the annual report of the State Board of Health for that year, containing chemical analyses of the sewage and effluent from the works at the three places described, viz., Framingham, Marlborough and Gardner. In the annual report of the Board for the year 1893 there appeared a corresponding paper, in which were given the results of analyses of sewage and effluent up to Jan. 1, 1894, from these three and several additional sewage-purification plants, together with a brief description of each of the systems.

In the present paper will be found analyses made during the years 1894 and 1895 of the sewage and effluents from the works at Amherst, Brockton, Framingham, Gardner, Marlborough and Medfield. A short description of the works at each place is given in connection with the analyses, and in some cases statements made in previous reports are repeated.

The first plant for the disposal of town sewage by filtration in Massachusetts was constructed at Lenox in 1876. A system for the disposal of the sewage of a portion of the town of Amherst, partly by filtration but chiefly by irrigation, was constructed about 1881, and a small system for the disposal of sewage by intermittent filtration was introduced at Medfield in 1886. Since the last date the towns of Framingham, Gardner and Westborough and the cities of Marlborough and Brockton have constructed and are now operating works for the disposal of sewage by intermittent

filtration, and a new disposal field has been constructed and is in use at Lenox. At North Brookfield there is a small system of sewage disposal by irrigation and filtration. There are also in the State several large institutions which dispose of their sewage by intermittent filtration.

The sewage of the city of Worcester is treated with chemicals, and the method has been fully described under "Blackstone River," in the chapters on the examination of rivers in previous reports of the Board, and on page 367 of this volume. Analyses made by the chemists at Worcester, showing the results obtained at the chemical precipitation works there, have already been given on page 372 of the report for 1894 and on page 360 of the present report.

In addition to the analyses given in the following pages, there have also been collected hourly samples of sewage, representing the entire flow for twenty-four hours in the main sewers at Framingham, Gardner, Marlborough and the Worcester Lunatic Asylum. The results of chemical and bacterial analyses of these samples have been presented and discussed in the chapter on the composition of sewage, in the report of the investigation upon the purification of sewage at the Lawrence experiment station, on page 462 of the annual report for 1894 and on page 452 of this volume.

#### SEWAGE DISPOSAL AT AMHERST.

The population of the town in 1895 was 4,785. Sewerage facilities have been provided only for portions of the main village, and the sewage is disposed of by two systems.

The first system, begun in 1881 and subsequently extended, collects the sewage from about 1,000 persons. The system is of the so-called "separate" type, which provides for house sewage only. The sewage flows to a settling tank about a mile south-east of the village, and thence through a pipe 520 feet long into Fort River. The settling tank into which it discharges has two compartments, each 10 feet wide, 15 feet long and 6 feet deep, constructed of stone laid in cement. The main sewer, which is 10 inches in diameter, branches just before it enters the tank, so that the sewage may be diverted into either compartment separately, delivering it at the surface of the sewage in the tank, which is about 1 foot below the top of the tank. The sewage is not screened, but the mouth of the outlet pipe turns downwards below the surface of

the sewage, so that some of the floating matter is retained in the tank. At irregular intervals the sludge is removed and mixed with soil, to be used as a fertilizer on the adjoining fields.

In the annexed table are the results of analyses of sewage before and after passage through the tank. It is to be noted that the effluent appears to represent sewage more dilute than that collected from the inlet pipe, so that the apparent purification was probably greater than that which actually took place. Analyses are also given of Fort River above and below the point of discharge of the effluent pipe.

The second system, which was begun in 1886, takes the sewage from a part of the thickly populated portion of the town, north of the town hall, to a settling tank and irrigation field half a mile north of the village. A description of this system, with results of analyses of sewage and effluent, was presented in the annual report for 1893. No analyses of the sewage or effluent have been made since that time.

Odor, none. On heating, the odor of the second sample was distinctly disagreeable. — The first sample was collected from the river, about 100 feet above the sewer outlet; the last, from the river about 200 feet below the sewer outlet.

### SEWAGE DISPOSAL AT BROCKTON.

The sewage disposal system of the city of Brockton (population in 1895, 33,165) was first put in operation in November, 1894, and at the close of that year there had been a few connections made with the sewers. At the end of December, 1895, there were 221 connections, 110 of which were from dwelling-houses, 67 from factories and the remainder from business blocks, hotels and public buildings. The total length of sewers constructed to the end of the year 1895, including the main sewer, was 13.82 miles.

The principal industry in Brockton is the manufacture of shoes. The city is situated largely in the valley of the Salisbury Plain River, into which nearly all of the drainage naturally flows, and a large proportion of the population is in the immediate vicinity of the stream. The watershed of the river just below the city is only about 16 square miles, and the sewage of the city could not be discharged into it without creating a nuisance.

The system of sewerage adopted is what is known as the separate system, and as it was necessary in this case to pump all of the sewage, all surface water has been excluded from the system and great care has been taken to exclude ground water both from the street sewers and the house connections. Under-drains were constructed beneath all sewers, during the construction of which ground water was en-

countered, and special care was taken to make all joints tight. The under-drains discharge directly into the river or its tributaries at convenient points. The main or intercepting sewer is laid in low land bordering the river; it is egg-shaped in section, and at its lower end its size is 32 inches by 48 inches. At times of high water there is considerable leakage into it, and before any sewage was admitted to the sewers there was a large flow of ground water from the outlet of the intercepting sewer.

The sewage passes from the intercepting sewer at the pumping station into a covered masonry reservoir 110 feet long by 44 feet wide, having a capacity of about 500,000 gallons, sufficient to store the night flow of sewage and making it necessary to pump only during the day. The reservoir is ventilated by means of a 15-inch pipe connecting with the chimney of the pumping station. Between the reservoir and the pumps the sewage is screened by passing between iron plates placed so as to have an open space between them of three-fourths of an inch. From the pumping station the sewage is forced through a cast-iron force main 24 inches in diameter and nearly 17,000 feet in length to the filtration area.

The filtration area is situated in the south-westerly corner of the city, and comprises about 30 acres, being a part of a large area of flat, sandy land, locally known as the "muster field," the greater part of which is situated within the limits of the town of Easton. On this field 23 filter-beds have been prepared, having an average area, exclusive of embankments, of 1 acre. The loam was removed from all the beds. The subsoil was entirely removed from 12 of the beds, partially removed from 6, while in 5 of the beds the subsoil remains over the sand. The loam and subsoil which was removed was used in making the embankments between the beds. The filtering material varies from a fine gravel to a very fine sand, with the coarser material generally nearest the surface.

Under 10 of the beds a stratum of clay was found at a depth of from 7 to 8 feet, and in these beds 4 lines of 5-inch under-drains were constructed just above the clay, discharging through a 15-inch pipe into a small brook, a tributary of the Taunton River.

Although provision was made for the separation and removal of a portion of the solid matter from the sewage at the reservoir, there has as yet been no necessity for such separation, as the amount of sewage is so small that all of it can be disposed of on the beds.

An agitator has been placed in the bottom of the reservoir, through which sewage from the force main is introduced under pressure and by means of which all the solid matter which may have collected on the bottom may be thoroughly mixed with the liquid portion of the sewage and thus conveyed to the pumps. In the early operation of the plant it was the custom to start the agitator when the pumps were started and there was a large body of sewage in the reservoir, but by this method the sludge was distributed through the whole volume of sewage, and it was found that the beds soon became clogged. At the present time the agitator is put in operation just before the reservoir is emptied, and consequently the entire body of sludge, mixed with a small amount of sewage, is delivered at the field at once. Except when crops are being grown the sludge is discharged upon a separate bed, and when thoroughly dried the residue is raked up and burned.

The force main is so constructed that for about one-quarter of its length the pipe slopes towards the beds; but when the pumps are not running there are about 250,000 gallons remaining in the end of the pipe nearest the pumping station, which amount is stored there until pumping is resumed. When the daily amount of sewage pumped is less than 250,000 gallons, none of the sewage pumped into the force main one day reaches the filtration area until the next day, and consequently it has become quite stale when it is applied to the beds.

The method of operation has been to apply about 80,000 gallons of sewage to one bed, and then allow the filter to rest for a day before another dose is applied. During times of high flow in the sewers the size of the dose is much increased, but it is said that there has been no difficulty in disposing of all of the sewage, and 4 of the 23 beds have never been used.

During the winter of 1894-95 some of the beds were left with level surfaces; but it was found that in these beds the surface froze to such an extent that sewage could not be disposed of upon them, and the only beds which could be used during the cold weather were those which had been furrowed during the preceding fall. Accordingly all of the beds in use during the winter of 1895-96 were furrowed, and notwithstanding the low temperature of the sewage when received at the field, no difficulty was experienced from freezing.

The following table, taken from the report of the city engineer of Brockton for 1895, gives the average amount of sewage disposed of and the temperature of the sewage as it reaches the beds :—

| MONTH.            | Average Daily Flow at Field (Gallons). | Temperature Sewage at Field. | MONTH.             | Average Daily Flow at Field (Gallons). | Temperature Sewage at Field. |

Odor, none. — The sample was collected from the under-drain near Pearl Street, and contains a large amount of ground water.

### SEWAGE DISPOSAL AT FRAMINGHAM.

The town of Framingham (population in 1895, 9,512) contains three villages, of which South Framingham is by far the most populous, and up to the present time is the only village sewered.

The sewerage system was put in operation near the end of the year 1889, and at the end of 1895 about 800 dwelling-houses and 50 business blocks, stores, factories, etc., were connected with the sewer. In addition to this, the sewage of the Women's Prison (population, about 350), located in the town of Sherborn just beyond the Framingham line, enters this system. The storm water is excluded from the sewers, and a continuous system of under-drains was laid beneath the principal sewers to collect and carry off the ground water. The amount of sewage flowing during a season of high rainfall, however, is fully three times the ordinary flow. The main under-drain, which formerly discharged into a brook feeding Lake Cochituate, now discharges into an open reservoir near the pumping station, from which it is pumped to some specially prepared filter-beds a short distance away from the station. The average daily amount of sewage pumped and purified during 1895 was about 400,000 gallons.

The sewage is collected in a pair of receiving reservoirs having a total capacity of 431,000 gallons, from which it is pumped through a cast-iron main, 12 inches in diameter and 9,740 feet in length, to the filtration area, located about  $2\frac{1}{2}$  miles north-east of the village of South Framingham. This area, a more detailed description of which, accompanied by a plan, may be found on page 560 of the annual

report of the Board for 1892, covers about 70 acres, much of which is quite level. The field is at an elevation of about 20 feet above Bannister Brook, which flows along its north-westerly border.

Three new filters, having an area of 4 acres, were constructed during the year 1894, making 13 beds with a total area of about 16 acres which have been specially prepared for sewage. About half of this area is under-drained to a limited extent.

During the summer nearly all of the filter-beds are planted with field corn (maize), and very satisfactory crops are obtained. A few other crops were raised to a small extent, some of which have been fairly satisfactory. The old beds upon which corn was grown were not disturbed after the last hoeing in the early part of July, and they have been found to give satisfactory results in cold weather, owing to the arrangement of the surfaces in hills and furrows, thus enabling a covering of snow and ice to rest on the hills, and reducing the exposure of the material in the furrows to frost.

The quality of the sewage and effluent from several different places may be seen by the tables of analyses on the following pages. The sewage is ordinary town sewage, discolored and somewhat modified at times by a considerable amount of spent dyes discharged into the sewers from the straw-goods factories in the town.

For the results of chemical and bacterial analyses, showing the variations at different hours of the day in composition of the summer sewage, and measurements of its quantity, reference is made to page 469 of the annual report for 1894 and to page 456 of this volume.

Odor, distinctly vegetable and mouldy. — The samples were collected from the brook, at the first road crossing below the sewage field.

### SEWAGE DISPOSAL AT GARDNER.

The Gardner sewerage system was put in operation about Aug. 1, 1891. At the end of 1895 there were 254 connections with the sewers. The population of the town in 1895 was 9,182. With the exception of roof water used for flushing purposes from a limited number of buildings at the upper ends of the sewers, surface water is excluded. Care was also taken during the construction of the system to exclude ground water by making tight joints between the sewer pipes; but no under-drains were placed beneath the sewers, and there is a considerable quantity of ground water mixed with the sewage. The quantity of sewage is not definitely known, but it is probably not far from 250,000 gallons per day in dry weather.

The tract of land purchased by the town for the disposal of sewage contains 16.9 acres. Much of the material upon this tract was found to be too fine for the filtration of sewage, and as a result the filter-beds are almost wholly artificial, being formed of the porous sand and gravel from a ridge upon this tract. There are 12 thoroughly under-drained filter-beds, having a total area of 1.4 acres; two supplementary beds, which are less porous and not under-drained, having a total area of 0.37 acre; and two other small, under-drained beds, containing together 0.14 of an acre. One of the last beds is

used to receive the sludge from the sludge tank and the other was constructed to receive the discharge from a blow-off located at the lowest point in the inverted syphon which conveys the sewage from the town across the valley of Pond Brook to the filter-beds. This bed, however, has not been used for several years, as it has been found that if clogging occurs in the syphon the sewage backs up in the pipe until sufficient head is obtained to remove the obstruction.

The material of the filter-beds has an effective size of 0.10 to 0.24 millimeters, which is somewhat coarser than that at Marlborough but much finer than that at Framingham. Under-drains beneath the beds are generally 20 feet apart, and at a depth of 4 to 5 feet below the surface of the beds. The sewage when it reaches the disposal area first passes through duplicate separating tanks, having combined capacity of about 10,000 gallons, and overflows through wooden troughs upon the disposal area, as described in the annual report of the Board for 1892, page 580.

The operation of these filter-beds in winter is very different from that in warm weather. During the warmer portions of the year it has been the general custom to apply the sewage to the beds in rotation once in two days, the amount applied depending upon the character of the material of the bed. The deposit which forms upon the surface of the filter is removed, and the surface of the sand raked to a depth of 2 or 3 inches, about once in ten days or two weeks. By this method of operation good purification has been obtained during the warmer portion of the year. In winter weather, when the amount of sewage is greater and it is impossible to remove the solid matter from the beds, the filters become greatly overtaxed, and a short time after severe winter weather sets in all of the beds are covered with the sewage and much of the time a large part of it overflows into the adjoining brook. When the warmer weather comes the surface of the beds becomes uncovered, the sludge which has accumulated during the winter is scraped off and the quality of the effluent rapidly improves.

The area of the filter-beds is inadequate for purification of the sewage of the town, and it will be necessary to prepare a larger number of beds in order to prevent unpurified or partially purified sewage from entering the brook.

During the last two winters the surfaces of the filters have been mowed, and the results obtained have been somewhat better than in previous years, although it appears that the night flow

during the winter finds its way into the brook without purification, and during the coldest weather much of the flow during the day cannot be taken care of by the filters.

During 1894 it was found that just beneath the surface the material had become very compact, and to remedy this the greater part of the filter area was worked over for a depth of 8 or 10 inches. Many small stones were met in this treatment, and holes several feet deep were dug in the filters, in which the stones were buried. As the few inches of material placed over the stones washed away to a certain extent, this process was an unfortunate one, because it gave an

\* Too turbid to determine.

opportunity for some of the sewage to reach the effluent pipe in a less purified state than should be the case.

The average analyses, as given in the following tables, indicate that of the sewage filtered, about 89 per cent. of the organic matter, as represented by the albuminoid ammonia, was removed by filtration during 1894, and about 90 per cent. during 1895. For the results of chemical and bacterial analyses, showing the variations at different hours of the day in composition of the summer sewage and measurements of its quantity, a reference is made to page 468 of the annual report for 1894.

*Sewage from Gardner.*

Iron, .0857. Odor, distinctly musty or unpleasant. — The samples were collected from the brook, below the filter-beds and below the point where effluent from the filter-beds enters the stream.

## SEWAGE DISPOSAL OF MARLBOROUGH.

The sewerage system of the city of Marlborough (population in 1895, 14,977) was completed late in 1891, and at the end of 1895 there were about 1,252 connections, including all of the larger buildings, such as hotels, factories, etc.; the total length of sewers was

22.07 miles. The so-called "separate system" was adopted, but no under-drains were laid beneath the sewers, and a large amount of ground water enters them at certain seasons of the year.

As the sewage arrives at the disposal field it passes through duplicate separating tanks and screens before passing into the distributing pipes. Each tank is about 25 feet long,  $6\frac{1}{2}$  feet wide and 6 feet deep. The screens are of wire, and have a 1-inch mesh. The sludge which is deposited in the tanks flows by gravity to beds prepared for this purpose.

The total area of the tract bought by the city is 62.7 acres. Upon this tract 13 sewage beds with a total area of 9.6 acres and 6 sludge beds with a total area of 1.7 acres have been prepared for the disposal of the sewage and sludge. The material of the beds is finer than that of Framingham or Gardner, and has an effective size of 0.12 to 0.14 millimeters. The area has a moderate slope toward a small brook, and is from 7 to 22 feet above it. The beds are thoroughly under-drained by means of parallel lines of pipe, 50 feet apart and about 6 feet beneath the surface. All these drains discharge into the brook before mentioned.

The sewage is ordinary city sewage, varying in strength from time to time with the amount of ground water which enters the sewers. The quantity of sewage is not known, but the dry weather flow is probably in the neighborhood of 500,000 gallons per day.

For the results of chemical and bacterial analyses of hourly samples, showing the variation in the summer sewage as it flowed into the settling tanks, reference is made to page 467 of the annual report for 1894 and page 455 of this volume. In the same tables hourly measurements of flow will also be found. Each bed generally receives the sewage for twenty-four hours, unless the quantity of sewage is so great as to cause it to overflow its banks; and the sewage disappears from the surface in from one to ten days after receiving the dose.

The surfaces are ploughed and harrowed about once in three weeks, the sludge being raked from the surface before the bed is ploughed. After this treatment the sewage disappears from the bed rapidly, the length of time taken for it to pass through the filter increasing with each application of sewage.

In the fall the surfaces of the beds are furrowed with a disc harrow and in the winter the sewage is applied to the beds for not more than half a day at a time. The capacity of the field, however,

is insufficient for the flow during wet weather. At such times a portion of the sewage flows directly into the brook.

The separating tanks are emptied once in two weeks, and the sludge, after being dried on the beds prepared for the purpose, is carted away by the farmers for use upon the land as a fertilizer.

It has not been the custom to employ a man constantly in caring for the beds, as in the cases of Brockton, Framingham and Gardner, but to employ a man living in the neighborhood to attend to changing the flow of sewage from bed to bed and to remove the scum from the surface of the beds, paying him by the hour for the

\* Too turbid to determine.

time spent on the work. The cost of all work done on the beds during 1895 amounted to about \$1,000.

At times there has been considerable odor from the sludge beds and around the outlet of the carriers, but this has been overcome somewhat by the use of lime. The average analyses for the year 1894, as presented in the following tables, indicate that about 95 per cent. of the organic matter, as represented by the albuminoid ammonia, was removed from that portion of the sewage which was applied to the beds during that year, and during 1895 the percentage of organic matter removed was about 93.

*Sewage from Marlborough.*

Iron, .0270. — The samples were collected from the brook, at the road crossing below

## SEWAGE DISPOSAL AT MEDFIELD.

A system of sewage disposal by intermittent filtration was introduced at Medfield in 1886, and was described in the nineteenth annual report of the Board for the year 1887. Up to the end of 1895 connections had been made with 1 hotel, 3 houses and a large straw factory, in which, at times, as many as 900 operatives are employed. The original area of the beds was about 1 acre. The material is mostly coarse gravel. As the level of the ground water is about 10 feet below the surface of the filter, there are no underdrains. There are 4 beds, the surfaces of which are somewhat uneven, each of which, as a general rule, takes the sewage in turn for two days. It was found that there was considerable loam a

*Effluent from the Marlborough Sewage Filter-beds is discharged.*

the filter-beds and below where the effluent from the filter-beds enters the stream.

short distance below the surface of a portion of the beds, which eventually became clogged. In the summer of 1893 this loam was removed and replaced with coarse gravel, and the area of the filter increased about one-third. Several times during the warm weather the surfaces were harrowed, but they have not been ridged for service in the winter.

No trouble has arisen from odors. In the following tables will be found analyses of the sewage, and of the effluent taken from a spring a short distance below the filter. The effluent is of excellent quality, and no marked deterioration is shown by the analyses when compared with those made in 1887, after the works had been in operation for a comparatively short time.

# FOOD AND DRUG INSPECTION.

---

---

## FOOD AND DRUG INSPECTION.

---

The following report comprises the operations of the Board under the provisions of the food and drug acts for the year ending Sept. 30, 1895.

The force employed by the Board during the year consisted of the following persons :—

|                                       |                           |
|---------------------------------------|---------------------------|
| Dr. CHARLES P. WORCESTER, . . . . .   | <i>Analyst.</i>           |
| Prof. CHARLES A. GOESSMANN, . . . . . | <i>Analyst.</i>           |
| Mr. ALBERT E. LEACH, . . . . .        | <i>Assistant Analyst.</i> |
| JOHN H. TERRY, . . . . .              | <i>Inspector.</i>         |
| JOHN F. McCAFFREY, . . . . .          | <i>Inspector.</i>         |
| HORACE F. DAVIS, . . . . .            | <i>Inspector.</i>         |
| THOMAS O. ALLEN, . . . . .            | <i>Inspector.</i>         |

In addition to the force employed in 1894, Mr. Thomas O. Allen was appointed by the Board in 1895, to act in the towns in the neighborhood of Lowell.

The whole number of samples of food and drugs (including milk) examined during the year was 7,309, or 435 more than the number examined in the year ending Sept. 30, 1894, and 1,405 more than the average annual number examined in the ten years from Sept. 30, 1885, to Sept 30, 1895.

The whole number examined since the beginning of operations in this department in 1883 was 67,756.

The following summary embraces the work done during the year :—

|                                                                |       |
|----------------------------------------------------------------|-------|
| Number of samples of milk examined, . . . . .                  | 3,794 |
| Number of samples above standard, . . . . .                    | 1,905 |
| Number of samples below standard, . . . . .                    | 1,889 |
| Percentage of adulteration or deficiency, . . . . .            | 49.8  |
| Number of samples of other kinds of food (not milk), . . . . . | 2,971 |
| Number of samples above standard, . . . . .                    | 2,379 |
| Number of samples below standard, . . . . .                    | 592   |
| Percentage of adulteration, . . . . .                          | 19.9  |

|                                                                      |      |
|----------------------------------------------------------------------|------|
| Number of samples of drugs examined, . . . . .                       | 544  |
| Number of samples of good quality, . . . . .                         | 212  |
| Number of samples adulterated, as defined by the statutes, . . . . . | 332  |
| Percentage of adulteration, . . . . .                                | 61.0 |

|                                                               |       |
|---------------------------------------------------------------|-------|
| Total number of samples of food and drugs examined, . . . . . | 7,309 |
| Total number found to be of good quality, . . . . .           | 4,496 |
| Total number not conforming to the statutes, . . . . .        | 2,813 |
| Percentage of adulteration, . . . . .                         | 38.5  |

Attention has already been called, in previous reports, to the fact that the percentages given in the foregoing summary do not represent, in any degree, the actual ratio of adulteration existing in food products and in drugs, for several reasons: chiefly on account of the fact that the experience of the Board enables it, first, to exercise a careful selection of such articles, mainly, as are liable to adulteration; secondly, to obtain such articles in those seasons of the year when their adulteration is most common; and third, to pay special attention to new forms of adulteration which are constantly appearing as fast as the fraud and ingenuity of the professional adulterator presents them to the public.

Legislation itself has an effect upon the ratio of samples found to be adulterated. For example, in 1885, 273 samples of vinegar were examined and 81 per cent. were found to be below the standard. Had these samples been examined in the following year, only 61 per cent. would have fallen below the standard, since the standard of acetic acid in vinegar was reduced by the law of 1885 from 5 per cent. to  $4\frac{1}{2}$  per cent. and about 20 per cent. of the number of samples were found to range between  $4\frac{1}{2}$  and 5 per cent.

The following tables present a summary of the work done during the entire period from the beginning of operations under the food and drug acts in 1883 to the close of the year ending Sept. 30, 1895:—

## STATISTICAL SUMMARY.

## FOOD AND DRUG INSPECTION (1888-95).

| SUMMARY.                                                                  | YEARS.     |            |            |            |            |            |             |            |            |             |
|---------------------------------------------------------------------------|------------|------------|------------|------------|------------|------------|-------------|------------|------------|-------------|

| Expense of collection, examination and prosecution, per sample, . . . . . | 1 67        | 1 80        | 1 80        | 1 63        | 1 52        | 1 56        | 1 72         |

The removal of the office of the Board, as well as the laboratory for food and drug analysis, to the present quarters under one roof at the State House has proved to be a matter of great convenience, since it not only allows a greater amount of work to be done, but also affords better opportunity for consultation between the Board and its analysts in all difficult and doubtful cases.

### MILK.

The great importance of milk as an article of food for all classes of people, and especially for the young, the ease with which its adulteration is accomplished and the difficulty of its detection by the ordinary consumer, constituted a sufficient reason for the legal requirement that a definite and comparatively large ratio of the expense of carrying out the provisions of the law should be employed in the inspection of milk and its products.

The questions pertaining to commercial fraud in the sale of milk products (milk, butter and cheese) are sufficiently provided for by existing laws, and there appears to be a tendency at the present time towards legislation in the more important direction of the sanitary control of the milk supply. The recent acts providing for the inspection of milch cows, and the destruction of such as are found to be diseased, undoubtedly give greater security to the consumers of milk.

While this is eminently desirable, it is quite as necessary that legislation should provide for prevention of the recurrence of disease in the future by requiring the frequent inspection, by competent authority, of the places in which dairy animals are kept for the production of milk, and that special attention should be paid to their housing, their water supply, the ventilation and drainage of their stables and the quality of their food.

During the past few years the Board has been called upon frequently to investigate the causes of outbreaks of typhoid fever, and in several instances the medium of infection has been found to be the milk supply. It is needless to add that carelessness in management and want of cleanliness in some of the details of dairy work were invariably found to exist in such cases. Local boards of health will accomplish much by encouraging the establishment of *model dairies*, in which milk is produced and prepared for sale under the best possible conditions. The cost of such milk may be a little higher to the consumer, but the security which is gained will pay in the end. The game is well worth the candle.

Several points in the reports of the analysts are worthy of note. The appearance, during the year, of a comparatively new coloring matter, employed in the adulteration of milk, has led to a careful investigation of its character and composition. The substance employed is an aniline dye, and the quantity required to produce the color of a rich milk is quite small. Fortunately, the dye is easy of detection when introduced into milk, as is shown in the report of the analyst.

Attention is called to the figures showing the results of analysis in a case where the analysis of nine samples was made by three chemists, the chemist of the Board and two others to whom the samples were submitted. The greatest difference in these analyses was only  $1\frac{12}{100}$  of one per cent.

The claim is often urged by milk producers that it is impossible to produce milk which shall uniformly satisfy the requirements of the law, and instances are adduced of single animals of some particular breed which produce milk of a quality considerably below the legal standard. To the influence thus produced by the employment of breeds which furnish milk of a low standard is added the effect of using impoverished food, which tends to increase the quantity of milk at the expense of its quality.

It is, however, rare to find a herd of cows, consisting, as is usually the case, of a variety of breeds, in which the average mixture of the milk of the dairy falls below the legal standard of solids. It is not an uncommon event to find that the milk taken on the street from wagons, under the ordinary conditions of delivery, is nearly or quite as good as that which is produced at the dairies.

The following is a fair sample of a single collection of milk made in one city in the month of July, when the legal standard is 12 per cent. :—

| INSPECTOR'S NUMBER. | Total Solids. | Wagon or Shop. | INSPECTOR'S NUMBER. | Total Solids. | Wagon or Shop. |
|---------------------|---------------|----------------|---------------------|---------------|----------------|
| 8421, . . .         | 13.94         | Wagon.         | 8443, . . .         | 13.50         | Wagon.         |
| 8423, . . .         | 13.10         | Wagon.         | 8445, . . .         | 12.27         | Wagon.         |
| 8425, . . .         | 12.00         | Wagon.         | 8447, . . .         | 13.35         | Wagon.         |
| 8427, . . .         | 12.70         | Wagon.         | 8449, . . .         | 12.64         | Wagon.         |
| 8429, . . .         | 12.74         | Wagon.         | 8451, . . .         | 15.67         | Wagon.         |
| 8431, . . .         | 12.23         | Wagon.         | 8453, . . .         | 12.82         | Wagon.         |
| 8433, . . .         | 12.77         | Wagon.         | 8455, . . .         | 12.40         | Wagon.         |
| 8435, . . .         | 13.03         | Wagon.         | 8457, . . .         | 12.84         | Wagon.         |
| 8437, . . .         | 13.46         | Wagon.         | 8459, . . .         | 12.64         | Wagon.         |
| 8439, . . .         | 12.60         | Wagon.         |                     |               |                |
| 8441, . . .         | 13.00         | Wagon.         | Average, .          | 12.98         |                |

A table of analyses of different brands of condensed milk is presented in the report, showing at the first glance a fairly uniform quality in the samples examined. Close inspection, however, shows considerable differences in their composition, so far as they relate to the original nutrient constituents of the milk from which the samples were made. For example, the proteids showed a maximum of 9.83 per cent. and a minimum of 5.95 per cent., the milk sugar a maximum of 20.06 per cent. and a minimum of 7.05 per cent., and the fat a maximum of 12.3 per cent. and a minimum of 7.4 per cent.

The average constituents of the thirty-three samples were as follows:—

|                                  |       |
|----------------------------------|-------|
| Total solids, . . . . .          | 72.32 |
| Water, . . . . .                 | 27.76 |
| Milk solids, . . . . .           | 32.37 |
| Cane sugar, . . . . .            | 39.94 |
| Milk sugar, . . . . .            | 13.01 |
| Proteids, . . . . .              | 8.10  |
| Fat, . . . . .                   | 9.69  |
| Ash, . . . . .                   | 1.58  |
| Fat in original milk,* . . . . . | 4.05  |

As is quite commonly the case, the prices at which these different brands were sold afforded no indication of their comparative quality.

#### LOCAL INSPECTION.

The statutes provide that in every city there *shall* be a local inspector of milk, while in the towns the law is permissive only. As the towns increase in population, especially in the metropolitan district, the number in which milk inspectors are provided by the municipal authorities annually increases, and thus greater protection is constantly afforded against the adulteration of this important food. It is desirable that every town having a population of more than five thousand inhabitants should appoint an inspector, and give him such support in carrying out the law as the subject demands.

#### BUTTER.

The fact that more than 97 per cent. of the samples of butter obtained by the inspectors (186 out of 191 samples) proved to be genuine is a fair indication of the methods of sale of this article in open market, and of the extent of adulteration or of illegal sales,

---

\* Assuming a standard of 9.3 per cent. for solids not fat.

since the inspectors in obtaining samples of butter at retail have diligently sought for places where adulteration would be most liable to exist.

#### LARD.

Special attention has been paid by the analyst to the examination of lard and to the different methods of detection of its two principal adulterants, — cotton seed oil and the fats of beef, — since the presence of adulterated lard in the cities of Massachusetts has increased quite recently to a considerable degree.

#### SPICES.

The examination of spices shows a wholesome state of the market as compared with that of 1883–84 (the beginning of operations under the food acts), when 65 per cent. of spices examined were found to be adulterated. The percentage of adulteration last year was 16.3 per cent., or about one-fourth of that which prevailed a dozen years since.

#### MAPLE SYRUP AND SUGAR.

These valuable products of the rock or sugar maple tree have been made the subjects of careful study, and some advance has been made in the matter of distinguishing the different varieties of sugar which closely resemble cane sugar in their chemical composition. The rough inspection afforded by the senses of sight, taste and smell still give important aid in the examination of these articles.

#### EGG SUBSTITUTES.

The analysis of these preparations shows how little reliance can be placed in the statements of the inventors or manufacturers of new or patent food preparations with reference to their actual nutrient value.

#### COOKING UTENSILS.

While the food and drug act of Massachusetts does not provide, as in some countries, for the inspection of the utensils in which food is prepared for use, the Board has deemed it proper to make such investigations in this direction as may be necessary for the protection of the public. Considerable agitation having arisen during the year, as shown by comments in the newspapers, in regard to the possible danger which might arise from the use of “agate,” “gran-

ite" or enamelled ware, which is largely sold for culinary purposes, the Board ordered an examination to be made. It had been charged that the enamelled coating of such utensils contained arsenic. Arsenic was found in only one instance, and in that case the quantity was inconsiderable and such only as might have been due to a slight impurity in the material used for glazing. More than half of the utensils contained antimony.

---

The following figures afford a very good illustration of the advantages secured by the enactment of a well-devised food and drug statute.

In 1884, soon after the enactment of the law and before an adequate appropriation had been provided for its enforcement, an examination of spices and cream of tartar, and other articles of food, as sold in open market in Massachusetts gave the following results:—

Samples of spices collected in 1884, 431. Number adulterated, 216, or 50.1 per cent.

Samples of spices collected in July, 1896, 78. Number adulterated, 2, or 2.6 per cent.

Samples of cream of tartar collected in 1884, 232. Number adulterated, 77, or 33.2 per cent.

Samples of cream of tartar collected in July, 1896, 25, of which 1 was adulterated, or 4 per cent.

Out of 123 samples of butter, cheese, tea, coffee and confectionery collected in 1884, 15, or 12.2 per cent., were adulterated.

Out of 82 samples of the same articles collected under similar conditions in July, 1896, all proved to be genuine.

### DRUGS.

The principal drugs found to be adulterated by the analyst are as follows:—

Ether, distilled water, extract of licorice, compound spirits of ether, spirits of nitrous ether (all below standard and more than half showing less than 50 per cent. of the required strength), the pharmacopœial wines and liquor, tincture of opium, official soap and mercuric ointment. Much greater care is necessary in the preparation of distilled water. Its use for preparing eye-lotions, for the solution of nitrate of silver and other salts, and many other purposes requiring pure water, calls for a carefully made article, and yet it was quite commonly found on analysis to be nothing but

the tap-water of the city or town supply, and in one instance it contained more impurities than ordinary sewage. It is needless to say that a conviction and fine followed close upon this sale.

### NOTICES.

The following are the names of the cities and towns to which warning notices were sent during the year, stating that the parties to whom they were sent were found to be retailing food and drugs which were below the required standard of purity.

This form of notice was adopted for the purpose of giving information to retailers, where there is presumptive evidence that they are not aware of the fact that the articles in question are below the standard quality required by the statutes. Such notices are not required by the statutes, and failure to receive them does not exempt the retailer from liability to complaint at court.

#### *Cities and Towns to which Notices were sent on Account of Adulterated Milk.*

## PROSECUTIONS.

In the reports of the last three years a condensed summary was presented, showing the number of prosecutions conducted in each year since the beginning of work under the food and drugs acts. The following table presents the same figures, with the addition of those for the year ending Sept. 30, 1895: —

*Number of Complaints entered in Court.*

| YEAR.        | Food<br>not including<br>Milk. | Drugs. | Milk. | Total. | Convictions. | Fines<br>Imposed. |
|--------------|--------------------------------|--------|-------|--------|--------------|-------------------|
| 1883, . . .  | —                              | 5      | 4     | 9      | 8            | —†                |
| 1884, . . .  | 2                              | 1      | 45    | 48     | 44           | —†                |
| 1885,* . . . | 50                             | 1      | 68    | 119    | 103          | —†                |
| 1886,† . . . | 10                             | —      | 10    | 20     | 19           | —†                |
| 1887, . . .  | 30                             | —      | 34    | 64     | 60           | —†                |
| 1888, . . .  | 22                             | —      | 43    | 65     | 61           | \$2,042 00        |
| 1889, . . .  | 74                             | —      | 66    | 140    | 124          | 3,889 00          |
| 1890, . . .  | 78                             | —      | 24    | 102    | 96           | 3,919 00          |
| 1891, . . .  | 96                             | 5      | 49    | 150    | 135          | 2,668 00          |
| 1892, . . .  | 52                             | 12     | 72    | 136    | 123          | 3,661 70          |
| 1893, . . .  | 26                             | 3      | 67    | 96     | 92           | 2,476 00          |
| 1894, . . .  | 14                             | —      | 76    | 90     | 77           | 2,525 00          |
| 1895, . . .  | 13                             | 11     | 68    | 92     | 86           | 2,895 30          |
| Totals, . .  | 467                            | 38     | 626   | 1,131  | 1,028        | \$24,176 00       |

\* To May 1, 1886.

† Four months only.

‡ No record kept.

Ratio of convictions to complaints, 90.9 per cent.

NOTE. — All complaints entered before May 1, 1886, were under the direction of the Board of Health, Lunacy and Charity, and all after that date were under the direction of the State Board of Health.

The following report was presented to the Legislature in January, 1896, in compliance with the provisions of the statutes: —

OFFICE OF THE STATE BOARD OF HEALTH,  
STATE HOUSE, BOSTON, Jan. 9, 1896.

*To the Honorable Senate and House of Representatives of the Commonwealth of Massachusetts in General Court assembled.*

The following summary is made in compliance with the provisions of chapter 289, section 2, of the Acts of 1884, requiring the State Board of Health to "report annually to the Legislature the number of prosecutions made under chapter 263 of the Acts of 1882, and an itemized account of all money expended in carrying out the provisions thereof."

The whole number of prosecutions made by authority of the Board against offenders, under the provisions of the food and drug acts, for the year ending Sept. 30, 1895, was 92.

The cities and towns in which the articles were sold, and in respect to which complaints were entered in court, the character of the articles found to be adulterated, or fraudulently sold, the dates of the trials and their results, are presented in the following table:—

## SUMMARY.

The whole number of complaints entered by the State Board of Health during the year ending Sept. 30, 1895, in the courts of the Commonwealth, against parties for violation of the statutes relating to food and drug inspection, was 92.

---

\* Parties left the State before case could be tried.

In 86, or 93.5 per cent., of these the parties were convicted. Four were discharged either in the district, municipal or superior courts, and in two cases the parties had left the State before warrants could be served.

Of the whole number, 66 were for violation of the laws relating to milk adulteration, and of this number 63 resulted in conviction. The greater number of these was for violation of the statute providing that milk offered for sale shall be of good standard quality.

In 1 of the foregoing cases the complaint was for sale of milk from a can not properly marked, 5 cases were for sales of milk containing coloring matter, and 1 was for a sale of milk containing boracic acid.

In one of the cases the defendant was discharged because his counsel would not admit the affidavit of the chemist as evidence.

In another case, in which the complaint was made for a sale of adulterated coffee, the defendant was discharged because the judge decided that it was not necessary to mark retail packages as "compound" in cases where the article was bought in bulk from a larger box or bin, to which the word "compound" was affixed.

The attention of the Legislature is respectfully called to the fact that, in consequence of the enactment of chapter 425 of the Acts of 1894, "relative to the inspection of milk," the defendants in two cases of milk adulteration which recently occurred in Franklin County were discharged. The actual amount of adulteration in these two cases was excessive, amounting to 40 or 50 per cent. of the samples in question.

Of the 13 complaints for fraudulent sales of other kinds of food, all of the parties were convicted except one. The articles of food embraced in this list were as follows:—

Molasses, 1 case; coffee, 4 cases; mustard, 2 cases; cream of tartar, 1 case; honey, 1 case; pepper, 1 case; cassia, 1 case; lard, 1 case; maple syrup, 1 case.

The standard of whole milk in Massachusetts is 13 per cent. of solid residue, except in May and June, when it is 12 per cent. The following list presents the total solids in all the samples of milk upon which complaints were founded, so far as records of the same were kept:—

|      |       |       |       |       |
|------|-------|-------|-------|-------|
| 6.66 | 10.24 | 10.63 | 11.05 | 11.42 |
| 7.44 | 10.26 | 10.72 | 11.12 | 11.46 |
| 8.79 | 10.30 | 10.80 | 11.16 | 11.46 |
| 8.90 | 10.38 | 10.84 | 11.16 | 11.57 |
| 9.22 | 10.38 | 10.86 | 11.18 | 11.58 |
| 9.60 | 10.40 | 10.86 | 11.26 | 11.65 |
| 9.63 | 10.42 | 10.87 | 11.27 | 11.66 |
| 9.84 | 10.47 | 10.87 | 11.28 | 11.70 |
| 9.87 | 10.56 | 10.90 | 11.30 | 11.80 |
| 9.89 | 10.56 | 10.90 | 11.35 | 11.89 |
| 9.92 | 10.58 | 10.92 | 11.37 | 11.93 |
| 9.92 | 10.62 | 10.92 | 11.40 | 12.46 |

total number of samples of food and drugs examined during the year as follows:—

|                                                      |             |
|------------------------------------------------------|-------------|
| articles of food,                                    | 3,712       |
| drugs,                                               | 2,971       |
| total,                                               | 544         |
| expenses of collection, examination and prosecution, | 7,227       |
| per expense per sample collected,                    | \$11,375 89 |
|                                                      | 1 57        |

#### FINES.

amount of fines paid into the treasuries of counties, cities and towns under the provisions of the general and special laws relative to the inspection of food and drugs was as follows:—

*paid for Violation of the Food and Drug Acts, upon Cases entered for the Year ending Sept. 30, 1895.*

|                                                                          |            |
|--------------------------------------------------------------------------|------------|
| the provisions of the laws relating to milk and milk products,           | \$2,652 62 |
| the provisions of the laws relating to other articles of food and drugs, | 242 68     |
| total,                                                                   | \$2,895 30 |

#### EXPENDITURES

## REPORTS OF THE ANALYSTS.

---

---

# REPORTS OF THE ANALYSTS.

Dr. S. W. ABBOTT, *Secretary of the State Board of Health.*

DEAR SIR:—I have the honor to report the analysis of food and drugs for the year beginning Oct. 1, 1894, and ending Sept. 30, 1895.

## MILK.

The number of samples of milk analyzed in the State House laboratory during the year was larger than that of any previous year, and includes all the milk collected by the three inspectors of the Board throughout the State, exclusive of that from the four western counties, the examination of which is done at Amherst.

As usual, the total solids of every sample of milk submitted to us were determined gravimetrically, and those found below 12 per cent. total solids were further analyzed for fat. The methods of analysis were the same as those employed in previous years, viz., the determination of the solids by evaporation and of the fat by means of the Babcock process.

A careful examination was also made in suspected cases for color, preservatives, etc.

The ratio of samples found to be below the standard for the year is shown to be 51.5 per cent., being nearly identical with that of the preceding year, which was 51 per cent.

The following table shows the quality of the milk by months, and the percentage of adulteration of each month, corresponding to a standard of 13 per cent. and 12 per cent. respectively:—

*Quality of Milk by Months.*

| MONTHS.              | Total Samples Collected. | Above 13 Per Cent. | Below 13 Per Cent. | Below 12 Per Cent. | Ratio below 13 Per Cent. Standard. | Ratio below 12 Per Cent. Standard. |
|----------------------|--------------------------|--------------------|--------------------|--------------------|------------------------------------|------------------------------------|
| October, . . . . .   | 265                      | 120                | 145                | 43                 | 54.7                               | 16.2                               |
| November, . . . . .  | 165                      | 87                 | 78                 | 17                 | 47.3                               | 10.3                               |
| December, . . . . .  | 225                      | 111                | 114                | 20                 | 50.7                               | 8.8                                |
| January, . . . . .   | 252                      | 126                | 126                | 31                 | 50.0                               | 12.3                               |

| September, . . . . . | 393                      | 117                | 276                | 83                 | 70.2                               | 21.1                               |
|                      | 3,549                    | 1,377              | 2,172              | 579                | 51.2                               | 16.3                               |

It will be seen that under a standard of 13 per cent. throughout the entire year the ratio of samples below the standard would be 61.2 per cent., while with a 12 per cent. standard for the year the ratio would be only 16.3 per cent., so that the relative showing for the year is largely dependent on legislative enactment.

The following tables show the sources of the various samples of milk examined, apportioned among the cities, towns and suspected producers :—

|                                | 3,649                    | 1,720           | 1,829           | 51.5                      | 6.66                           | 32                         | 38                        |

The number of milk samples collected from producers was considerably larger than usual, and a much larger number of towns than usual is included in this list.

The number of colored samples found during the year is unusually large. Annatto was the favorite coloring matter employed. While in most instances the color was added to conceal evidence of watering, a number of cases were found in which the milk itself was considerably above the standard, though containing added coloring matter.

Several samples of milk were found to contain an added coal tar color. It was found to be a mixture of two or more of the orange members of the diazo compounds of aniline. A mixture of the dyes known to the trade as "Orange G" and "Fast Yellow" gives a color which is essentially identical with this milk color.

For its detection in the milk it was found sufficient to curdle about half a pint of the heated milk with acetic acid, so as to separate the casein in one mass. The whey being poured off, the orange dye, if present, is readily detected in the curd by macerating with ether for some time, preferably over night. The natural color of the milk left in the curd is entirely dissolved out by the ether, as is annatto or any of the common vegetable coloring matters, leaving the curd a pure white. The coal tar dye, on the contrary, is not dissolved out by ether, and, on pouring off the latter, the dye is readily apparent, if present, by the persistent deep yellow or orange color of the curd.

Among a number of samples of milk brought in by one of the inspectors was found a sample can containing water colored with caramel, with the addition also of common salt. This colored water, it was afterwards ascertained, was found by the inspector in an eight-quart can nearly full, among a number of milk cans in a dealer's wagon. Its obvious use was to both water and color at the same time milk delivered in small cans from house to house. This method of treating the milk at the time of its delivery was doubtless considered by the dealer as a very clever dodge, in that the milk taken from his wagon would undoubtedly be found to be of good quality.

The lowest sample of milk analyzed this year contained 6.66 per cent. total solids, of which 2.25 per cent. was fat. This was taken from a farmer, and was one of a lot of milk samples which was, with one exception, the worst lot ever analyzed by the Board.

Bearing on the question so often asked in court as to the degree of accuracy attainable in parallel analyses of the same milk, and as to the closeness of agreement in analyses of the same milk by different chemists, an opportunity was afforded during the year to practically test this point.

A certain milk dealer was suspected of having tampered with sealed samples of milk given him by an inspector to the extent of removing the milk contained in the sealed bottles delivered to him by the inspector (which milk was of poor quality) and replacing it by other milk of good quality, afterwards fixing the seals so as not to be detected, and taking the samples to an outside chemist for analysis. The wide difference in the results obtained by the outside chemist and those of the Board's analyst (amounting in one case to about 3 per cent. of milk solids) led to a second raid on the dealer by the inspector, who was instructed to make several sealed samples of each milk taken, in order that check analyses might be made by different chemists. Following is a summary of the results in percentage of total solids obtained and reported independently by three analysts on the nine samples of milk so taken : —

|          |       |       |       |          |       |       |       |
|----------|-------|-------|-------|----------|-------|-------|-------|
| A, . . . | 13.10 | 13.11 | 13.02 | F, . . . | 13.64 | 13.60 | 13.62 |
| B, . . . | 12.60 | 12.54 | 12.50 | G, . . . | 14.03 | 13.90 | 13.96 |
| C, . . . | 12.74 | 12.76 | 12.78 | H, . . . | 12.42 | 12.42 | 12.40 |
| D, . . . | 12.84 | 12.77 | 12.78 | I, . . . | 12.62 | 12.69 | 12.70 |
| E, . . . | 11.42 | 11.43 | 11.46 |          |       |       |       |

None of the milk samples examined during the year were found to contain any added preservative.

#### *Condensed Milk.*

The accompanying table shows the results of the analysis of as many brands of condensed milk as could conveniently be obtained. The quality of the milk used is shown to be in nearly every instance all that could be desired, and it would seem as if the popular idea that condensed milk is usually made from skimmed milk is erroneous.

The method of analysis employed, adapted from that of H. B. Cornwall, consisted in first weighing out 40 grammes of the thoroughly mixed sample and making up to 100 cubic centimeters with water. Portions of this solution were taken for the various determinations, as follows :—

*Total Solids.*—An aliquot part of the above 40 per cent. solution was further diluted with an equal amount of water, and 5 cubic centimeters of the diluted mixture (corresponding to 1 gramme of the condensed milk) was evaporated, dried and weighed in a platinum dish.

*Ash.* — The residue from the total solids as above obtained was burned and weighed.

*Fat.* — Five cubic centimeters of the 40 per cent. solution (corresponding to 2 grammes of the condensed milk) was absorbed by a coil of filter paper which was dried in an air oven at 100° C., and the fat extracted by ether in a Soxhlet extractor.

*Proteids.* — Five cubic centimeters of the 40 per cent. solution was further diluted to about 40 cubic centimeters, and just enough of a very weak solution of copper sulphate was added to precipitate the albuminoids, which slowly settled, leaving a perfectly clear solution of the whey, free from copper. The precipitate was filtered through a weighed filter, washed and afterwards dried in the air oven and weighed. The filter with the dried precipitate was then incinerated in a porcelain crucible, and the weight of the ash minus that of the dried precipitate gave the weight of the proteids and fat. Deducting the percentage of fat, already obtained, from that of the proteids and fat, left the percentage of proteids.

*Milk Sugar.* — The filtrate and the washings from the preceding operation were made up to 100 cubic centimeters with water, and the amount of reducing sugar obtained volumetrically by Fehling's solution was reckoned as milk sugar.

*Cane Sugar.* — This was obtained by difference, deducting the total milk solids (milk sugar + proteids + fat + ash) from the total solids first obtained.

*Condensed Milk.*

### BUTTER.

Of 191 samples 186 proved to be genuine.

The Zeiss refractometer has been largely used in quickly detecting the admixture or substitution of margarine. Samples that the refractometer indicated as containing margarine were analyzed by the Reichert process in confirmation.

### CHEESE.

Thirteen samples were found of good quality. One sample of skim-milk cheese was found.

### LARD.

The analysis of lard both in this country and abroad has recently attracted much attention, and many methods have been devised for detecting admixture of beef fat and cotton-seed oil, the chief adulterants. The tests chiefly relied upon in this laboratory have been the following:—

*Reaction with Strong Acid (Sulphuric or Nitric.)* — Genuine lard and beef tallow usually give but slight coloration, while mixtures of cotton-seed oil invariably give a red-brown color, more or less intense in proportion to the amount of cotton-seed oil present.

A genuine lard will, however, occasionally be found to give a strong color with acid.

*The Microscopic Examination of the Stearin Crystals Separated from an Ether-Alcohol Solution.* — The characteristic crystalline forms of lard and tallow stearin are shown in figs. 1, 2 and 3.

*The Hehner Modification of the Bechi Nitrate of Silver Test.* — A small amount of the sample is shaken with half its bulk of a standard alcoholic solution of nitrate of silver, made very slightly acid with nitric acid. The vessel containing this mixture is then immersed in boiling water for fifteen minutes. With proper precautions the presence of cotton-seed oil is indicated by a strong reduction of the silver, while pure lard or tallow in the absence of cotton-seed oil causes no appreciable reduction.

*The Refractometer Reading.* — The refractometer used is the Zeiss instrument, in which the degree of refraction of a reflected beam of light which passes obliquely through a thin film of the fat

read on an arbitrary scale. A constant temperature by means of circulation of heated water is maintained and its degree is noted. The refracting degree of cotton-seed oil is about 8.9 in excess of the standard refraction of lard, while that of tallow is about 3.8 less than the standard. This is shown by samples H and I in the following table.

The readings are quickly and easily taken, and, in connection with the positive Bechi test for cotton-seed oil and the crystallization test for beef stearin, the refractometer is of great value.

It will be noted that adulteration of lard with cotton-seed oil alone is indicated by an abnormally high refractometer number, while the presence of tallow will result in an abnormally low refraction. But both adulterants may be present and a normal refraction result. In such a case the positive detection of one of them, such as the cotton-seed oil by the Bechi test, will indirectly show the presence of the other (tallow), and this indirect proof will be confirmed by crystallization.

*The Iodine Absorption Number.* — This is perhaps the most important of all the tests, although its results are in general prefigured by the refractometer. By it is meant the percentage of iodine which a sample of fat will absorb.

As may be seen in the following table, cotton-seed oil (H) will absorb about 108 per cent. of its weight of iodine, while beef fat (I) will absorb but about 37 per cent.

*Table showing Analysis of Samples, Illustrating Types of Lard and its Substitutes.*

|   | ACID REACTION.         | Crystallization.     | Bechl Reaction. | REFRACTOMETER.    |        |                                | Iodine Number. | Conclusion.                               |

4

1. Crystals of pure Leaf Lard Stearin.
2. Crystals of pure Back Lard Stearin.
3. Crystals of pure Beef Tallow Stearin.
4. Ground Pepper adulterated with ground Olive Stone.

Samples A, B and C give reactions corresponding to normal pure lard. D, E and F show somewhat high refractometer and iodine numbers but give no direct reaction for cotton-seed oil by the Bechi test. G, although showing low iodine and refractometer numbers, gives no evidence of the presence of tallow by crystallization. In fact, the crystals from this sample proved, under all circumstances, to be most clearly typical of pure lard, — broad and flat plates with obliquely cut ends.

This sample was, in fact, a pure leaf lard. It has been our experience that a stiff, strictly pure leaf lard, which both by its consistency and by its low iodine and refractometer numbers might suggest the presence of beef fat, shows, on crystallization, much more definitely characteristic lard stearin than does a whole hog lard, whose iodine and refractometer numbers are more nearly the normal standard.

In distinction from such a leaf lard, a sample which may have similar consistency and iodine and refractometer numbers, but which is composed of a whole hog lard of a comparatively high iodine number, together with beef fat, gives unmistakable proof of its adulteration by its crystallization.

Fig. 1 shows the crystalline form of pure leaf lard stearin; Fig. 2, of whole hog lard stearin; Fig. 3, of beef tallow stearin.

The adulteration of lard with tallow and cotton-seed oil is wholly unobjectionable as far as the wholesomeness of the compound is concerned. It is objectionable only on the ground of fraud, and is legally permissible provided the mixture is properly labelled.

#### OLIVE OIL.

Forty-two samples proved to be genuine and 9 were found to be adulterated with cotton-seed oil.

#### VINEGAR.

Thirty-two samples were of standard quality and 32 were inferior.

These figures indicate great carelessness as well as fraud in putting up this standard article.

The adulteration of vinegar is chiefly practised outside of Boston, in which city the vigorous enforcement of the law has resulted in the practical suppression of the sale of an inferior article. The report of the inspector of milk and vinegar for 1894, states that, of

938 samples examined, but few failed to conform to the statute requirements, and that dealers in spurious cider vinegar have abandoned Boston as a field of operations. It is to be hoped that a vigorous enforcement of the vinegar law throughout the State will result in driving such dealers out of the Commonwealth.

The definite standards fixed by statute render conviction under the vinegar law comparatively easy.

#### SPICES.

As usual, a large number of ground spices have been examined microscopically and chemically for adulteration.

One thousand and nineteen samples were found pure and 166 adulterated. The extent of adulteration varied from a trace up to 90 per cent.

Spices are very largely adulterated in other States, where a pure food law is not enforced. In this State, when the work of inspection was begun, 65 per cent. of the samples submitted were found to be adulterated. The great and nearly uniform decrease of adulteration of spices since that time may fairly be credited in large part to systematic and persistent public food inspection. The legalized sale of adulterated goods under the name of compounds still continues to a limited extent, with more or less attempt to conceal the real nature of the articles; but there appears to be a healthy and growing demand for guarantees of strict purity among small dealers and consumers.

#### *Allspice.*

Ninety-eight genuine, 4 adulterated. The adulterants found were wheat and nutshells.

#### *Cassia.*

One hundred and forty-six genuine, 2 adulterated. The adulterants found were wheat, corn, nutshells and turmeric.

#### *Cayenne.*

Seventy-three genuine, 34 adulterated. The adulterant found was chiefly corn, but admixtures of wheat, rice, turmeric and salt were also found.

#### *Cloves.*

One hundred and ninety-three genuine, 15 adulterated. The adulterants found were wheat, corn, rice, nutshells, turmeric and clove stems.

*Ginger.*

One hundred and thirty-four genuine, 22 adulterated. The adulterants found were wheat, corn and turmeric. The fancy for deeply coloring this spice with a liberal mixture of turmeric is hardly less frequently met with than in the case of mustard.

*Mace.*

Sixteen genuine.

*Mustard.*

One hundred and twenty-seven genuine, 71 adulterated. The adulterants found were wheat, corn, rice, turmeric, cayenne and gypsum. The "terra alba" was found in one sample to the extent of 21 per cent.

*Nutmeg.*

Six genuine.

*Pepper.*

Two hundred and twenty-six genuine, 17 adulterated. The adulterants found were corn, wheat, rice, ginger, cayenne, grains of paradise, nutshells and buckwheat. Several samples were found to be largely adulterated with woody stone cells, identical with those of the olive stone. Fig. 4 shows the microscopic appearance of one of these samples. This adulteration has been reported found in other localities but it has not been found here before.

## COFFEE.

Seventy-nine genuine, 19 adulterated. The adulterants found were peas and pea hulls, chicory, wheat, straw, sticks, glass and artificial grains made of a roasted wheat mash.

## CREAM OF TARTAR.

Three hundred and sixty-four genuine, 12 adulterated. The adulterants found were starch (wheat and corn), acid phosphate of calcium and gypsum. One sample contained 85 per cent. of the last-named substance.

## HONEY.

Forty-one genuine, 2 adulterated. The adulterant found was glucose syrup.

## MOLASSES.

Two hundred and twelve genuine, 13 adulterated. The adulterant found was glucose syrup.

### MAPLE SUGAR.

Forty genuine, 7 adulterated. The admixture or substitution of a crude brown cane sugar for maple sugar is of frequent occurrence in the spring, when "maple sugar" is to be found in nearly every market or fruit stand, grocer's or confectioner's shop. There is, of course, no valid objection to the sale of a cheap brown sugar moulded into cakes, provided it is not sold as maple sugar and at its comparatively high price.

It is not a difficult matter to distinguish between maple sugar and the "brown sugar" of the grocers' shops by appearance, by odor, particularly when boiled with water, and by taste. Chemically the distinction between the two is facilitated by the fact that the juice of the sugar cane contains from 0.15 to 2 per cent. of albuminous matters, while the sap of the maple tree contains but about 0.01 per cent. of albuminoids.

Notwithstanding the fact that the dilution of the maple sap is greater than that of the cane juice, the fact remains that the ratio of albuminous matters to total solids of the cane juice is greater than that of the maple sap.

The greater sulphur contents of the grocers' brown sugar, which may readily be determined, is apparently due to this cause.

The potash in the ash of sugar from the cane has always been accompanied in our experience by a notable proportion of sodium salt, while the soluble ash of maple sugar has proved nearly pure potash.

### MAPLE SYRUP.

Twenty-seven genuine, 3 adulterated. The adulterant found was glucose syrup.

### TEA.

Eighty-five genuine, 6 inferior. Two samples of compressed tea tablets were examined, with the following widely different results:—

|                                    | A    | B    |
|------------------------------------|------|------|
| Total hot water extract, . . . . . | 19.5 | 54.4 |
| Water, . . . . .                   | 5.05 | 8.7  |
| Insoluble ash, . . . . .           | 4.45 | 2.6  |
| Soluble ash, . . . . .             | 3.45 | 2.8  |
| Theine, . . . . .                  | —    | 2.25 |

### FOOD PRESERVATIVES.

Samples of canned, bottled and dried foods of various kinds have been examined for artificial preservatives. Among those containing borax or boracic acid were samples of shredded codfish, oysters and clam juice.

Notable amounts of salicylic acid were found in many brands of tomato catsup, grape juice, strawberry jam, mince and apple preparations for pies, lager beer and fruit syrups.

A salt sold on the fish wharves as a "fish preservative" proved to be a mixture of common salt and borax. An "oyster preservative" proved to be a mixture of salt and boracic acid.

### EGG FOODS.

Samples of egg foods were examined, with the following results. They purported to be the equivalents in all respects of fresh eggs. A ten-cent package of sample A, for instance, weighing about two ounces, is announced to be equal to twelve eggs, whether of the domestic fowl or not is not specified.

|                                         | A     | B     | C     |
|-----------------------------------------|-------|-------|-------|
| Protein, . . . . .                      | 16.94 | 18.72 | 48.15 |
| Fat, . . . . .                          | 3.43  | 3.40  | 40.56 |
| Water, . . . . .                        | 6.71  | 7.01  | 5.95  |
| Corn starch, salts and coloring matter, | 72.92 | 70.87 | 5.34  |

Another sample was found to contain 29.9 per cent. of sugar.

It will be noted that the composition of sample C corresponds closely to the analysis of dried eggs, which contain of proteid, 54 per cent. ; fat, 40 per cent. ; salts, 5 per cent.

A sample of barberry preserve which had been boiled in a copper kettle was found to contain .003 grams of copper per 100, calculated as the sulphate.

Samples of extract of vanilla were examined by Merck's method. Ten were found to contain from .87 to 2.23 grams of vanillin per litre. Two others were found to contain coumarin.

Samples of fruit jellies were found to be composed of a cheap cider jelly variously modified by neutralizing and artificially coloring and flavoring to represent currant, blackberry, etc.

Thirty-seven samples of granite-ware dishes were examined. They comprised a great variety of articles, a large number of which were for use as cooking utensils. When thus used, particularly with acid contents, the metallic constituents of the glaze are dissolved quite readily. Of these cooking utensils the glaze was found in 23 instances to contain notable quantities of antimony and in 1 instance a small trace of arsenic; 10 contained tin. The glaze of 12 was found to be properly composed of harmless silicates.

A considerable number of samples of a miscellaneous nature have been examined. Among them may be mentioned samples of tea, meat, etc., which were reported to have caused symptoms of poisoning. On examination they gave negative results.

Various pudding preparations, such as "Kustard" and "Desertine," were found to be essentially corn-starch, sweetened, colored and flavored.

A sample of "phosphated gelatine" proved very strongly acid, containing no less than 3.42 per cent. of phosphoric acid.

*Summary of Food Statistics.*

| Foods.                     | Genuine. | Adulterated. | Total. | Per Cent. of Adulteration. |

## DRUGS.

*Acidum Benzoicum*: 4 standard.

*Acidum Hydrobromicum Dilutum*: 1 standard.

*Acidum Tannicum*: 12 standard.

*Æther*: 5 standard; 8 inferior, containing too much alcohol.

*Alcohol*: 6 standard.

*Aqua Ammoniæ*: 10 standard; 1 inferior, containing too little anhydrous ammonia.

*Aqua Chlori*: 2 inferior; 1 sample contained no trace of chlorine.

*Aqua Destillata*: But little care appears to be taken to supply a good article. The amount of solid matters per 100,000 parts of water may be seen by the following table of results of samples examined:—

*Distilled Water (Parts of Solids per 100,000 of Water).*

|     |     |     |     |      |       |
|-----|-----|-----|-----|------|-------|
| 0.0 | 4.0 | 6.5 | 7.2 | 9.0  | 18.3  |
| 0.0 | 4.2 | 6.5 | 7.5 | 9.0  | 20.0  |
| 0.3 | 4.5 | 6.5 | 7.5 | 9.1  | 38.5  |
| 0.8 | 4.5 | 6.5 | 8.0 | 11.9 | 120.0 |
| 3.0 | 6.2 | 6.6 | 8.5 | 12.8 |       |

*Aqua Hydrogenii Dioxidii*: 2 standard; 2 inferior. The samples which failed to meet the Pharmacopœial requirements contained but 57.5 per cent. and 25 per cent. of the proper amount of peroxide.

*Argenti Nitras*: 7 standard; 1 inferior, containing a sodium salt.

*Bismuthi Subcarbonas*: 1 standard.

*Bismuthi Subnitras*: 7 standard; 2 inferior, containing traces of arsenic.

*Calx Chlorata*: 2 standard; 2 inferior. One of these samples contained but 12 per cent. of available chlorine. The Pharmacopœia demands 35 per cent.

*Cerii Oxalas*: 3 standard.

*Chloroformum*: 8 standard; 1 inferior.

*Creta Præparata*: 3 standard.

*Extractum Glycyrrhizæ*: 2 standard; 23 inferior, containing considerable amounts of corn starch.

*Glycerinum*: 2 standard.

*Iodoformum*: 1 standard.

*Lycopodium*: 1 standard.

*Magnesii Sulphas*: 2 standard.

*Morphinæ Sulphas*: 1 standard.

*Oleum Ætheris*: 1 inferior, consisting chiefly of amyl alcohol.

*Oleum Limonis*: 3 standard; 1 inferior.

*Oleum Morrhuæ*: 5 standard.

*Oleum Ricini*: 10 standard.

*Potassii Iodidum*: 1 standard.

*Pulvis Glycyrrhizæ*: 1 standard.

*Pulvis Glycyrrhizæ Compositus*: 1 inferior.

*Pulvis Opii*: The Pharmacopœia demands from 13 to 15 per cent. of morphine. Samples gave on analysis percentages of morphine as follows:—

|      |      |      |      |      |
|------|------|------|------|------|
| 17.3 | 15.6 | 14.7 | 14.2 | 13.4 |
| 16.5 | 15.0 | 14.6 | 14.1 |      |

*Pulvis Rhei*: 3 standard.

*Spiritus Ætheris Compositus*: 6 standard; 8 inferior, containing little or no heavy oil of ether, upon which the virtue of the drug depends.

*Spiritus Ætheris Nitrosi*: but very few samples showed even an approximation to the Pharmacopœial requirement in contents of ethyl nitrite. This drug cannot be properly kept unless in small, securely sealed bottles, away from the light, and even so it loses its strength in the course of years. Apparently but little care is exercised by druggists to observe these necessary precautions.

*Percentages of the Required Amount of Ethyl Nitrite referred to the Pharmacopœial Standard (100 per cent.) contained in Samples of Spiritus Ætheris Nitrosi.*

|    |    |    |    |   |
|----|----|----|----|---|
| 90 | 69 | 47 | 30 | 8 |
| 90 | 69 | 45 | 28 | 6 |
| 90 | 67 | 44 | 27 | 5 |
| 85 | 66 | 44 | 25 | 5 |
| 83 | 65 | 43 | 25 | 4 |
| 82 | 65 | 42 | 23 | 3 |
| 79 | 63 | 42 | 21 | 3 |
| 77 | 60 | 41 | 20 | 3 |
| 77 | 60 | 41 | 20 | 3 |
| 71 | 60 | 41 | 19 | 2 |
| 70 | 60 | 38 | 19 | 2 |
| 70 | 58 | 36 | 18 | 1 |
| 70 | 56 | 36 | 16 | 1 |
| 70 | 52 | 34 | 11 | 1 |
| 70 | 47 | 33 | 10 |   |

*Spiritus Frumenti*: 1 standard; 6 inferior, as shown below \* :—

| ALCOHOL (BY WEIGHT). | Extract. | ALCOHOL (BY WEIGHT). | Extract. |
|----------------------|----------|----------------------|----------|
| 44.55, . . . . .     | 3.24     | 42.48, . . . . .     | 0.48     |
| 44.24, . . . . .     | 0.74     | 37.22, . . . . .     | 0.16     |
| 42.95, . . . . .     | 1.00     | 37.17, . . . . .     | 0.20     |
| 42.86, . . . . .     | 0.54     |                      |          |

The high extract is due chiefly to added sugar.

*Tinctura Iodi*: 33 standard; 37 inferior, containing too little iodine.

*Tinctura Opii*: the Pharmacopœia demands from 1.3 to 1.5 per cent. of morphine.

\* The Pharmacopœial standard requires 44 to 50 per cent. of alcohol by weight, and not more than 0.25 per cent. of extract.

The samples analyzed contained the following percentages of morphine :—

|      |      |      |      |      |      |
|------|------|------|------|------|------|
| 1.63 | 1.26 | 1.14 | 1.00 | 0.94 | 0.84 |
| 1.50 | 1.25 | 1.11 | 0.98 | 0.94 | 0.82 |
| 1.48 | 1.23 | 1.08 | 0.98 | 0.93 | 0.78 |
| 1.43 | 1.23 | 1.08 | 0.97 | 0.91 | 0.76 |
| 1.37 | 1.23 | 1.07 | 0.96 | 0.90 | 0.68 |
| 1.35 | 1.18 | 1.05 | 0.96 | 0.89 | 0.67 |
| 1.35 | 1.16 | 1.04 | 0.96 | 0.89 | 0.53 |
| 1.28 | 1.15 | 1.03 | 0.95 | 0.88 | 0.43 |
| 1.27 | 1.15 | 1.00 | 0.95 | 0.88 |      |
| 1.26 | 1.15 | 1.00 | 0.95 | 0.84 |      |

*Sapo*: The Pharmacopœia prescribes a limit of 36 per cent. of water and tests by which an excess of free alkali and the presence of animal fats, which are prohibited, may be determined. The agreement of the samples examined with these requirements may be seen from the following table :—

| SAMPLE.       |  |  |  |  |  |  | Water. | Excess of Free Alkali. | Presence of Animal Fats by the Pharmacopœial Test. |
|---------------|--|--|--|--|--|--|--------|------------------------|----------------------------------------------------|
| 1, . . . . .  |  |  |  |  |  |  | 7.4    | Slight excess.         | None.                                              |
| 2, . . . . .  |  |  |  |  |  |  | 3.6    | None.                  | None.                                              |
| 3, . . . . .  |  |  |  |  |  |  | 4.1    | Much excess.           | None.                                              |
| 4, . . . . .  |  |  |  |  |  |  | 10.8   | Much excess.           | None.                                              |
| 5, . . . . .  |  |  |  |  |  |  | 7.1    | None.                  | Present.                                           |
| 6, . . . . .  |  |  |  |  |  |  | 9.0    | None.                  | Present.                                           |
| 7, . . . . .  |  |  |  |  |  |  | 7.1    | None.                  | Present.                                           |
| 8, . . . . .  |  |  |  |  |  |  | 5.9    | None.                  | Present.                                           |
| 9, . . . . .  |  |  |  |  |  |  | 9.8    | Much excess.           | Present.                                           |
| 10, . . . . . |  |  |  |  |  |  | 6.4    | Much excess.           | Present.                                           |
| 11, . . . . . |  |  |  |  |  |  | 6.4    | Much excess.           | Present.                                           |
| 12, . . . . . |  |  |  |  |  |  | 5.0    | None.                  | Present.                                           |
| 13, . . . . . |  |  |  |  |  |  | 9.4    | None.                  | None.                                              |
| 14, . . . . . |  |  |  |  |  |  | 9.1    | None.                  | None.                                              |
| 15, . . . . . |  |  |  |  |  |  | 5.4    | None.                  | Present.                                           |
| 16, . . . . . |  |  |  |  |  |  | 7.4    | Slight excess.         | Present.                                           |
| 17, . . . . . |  |  |  |  |  |  | 11.2   | None.                  | None.                                              |
| 18, . . . . . |  |  |  |  |  |  | 6.2    | None.                  | None.                                              |
| 19, . . . . . |  |  |  |  |  |  | 15.0   | Much excess.           | None.                                              |
| 20, . . . . . |  |  |  |  |  |  | 6.7    | Slight excess.         | Present.                                           |
| 21, . . . . . |  |  |  |  |  |  | 14.8   | Slight excess.         | Present.                                           |
| 22, . . . . . |  |  |  |  |  |  | 7.0    | None.                  | Present.                                           |
| 23, . . . . . |  |  |  |  |  |  | 8.3    | Much excess.           | Present.                                           |
| 24, . . . . . |  |  |  |  |  |  | 27.0   | Slight excess.         | Present.                                           |
| 25, . . . . . |  |  |  |  |  |  | 5.5    | Slight excess.         | Present.                                           |
| 26, . . . . . |  |  |  |  |  |  | 6.0    | Slight excess.         | Present.                                           |
| 27, . . . . . |  |  |  |  |  |  | 9.7    | Much excess.           | Present.                                           |
| 28, . . . . . |  |  |  |  |  |  | 7.5    | Slight excess.         | Present.                                           |
| 29, . . . . . |  |  |  |  |  |  | 10.6   | Slight excess.         | Present.                                           |
| 30, . . . . . |  |  |  |  |  |  | 4.9    | Much excess.           | None.                                              |
| 31, . . . . . |  |  |  |  |  |  | 2.4    | None.                  | Present.                                           |
| 32, . . . . . |  |  |  |  |  |  | 12.2   | None.                  | None.                                              |
| 33, . . . . . |  |  |  |  |  |  | 5.8    | None.                  | None.                                              |

*Unguentum Hydrargyri*: the Pharmacopœia demands 50 per cent. of mercury. The percentages of mercury found in the samples examined were as follows :—

|    |    |    |    |     |
|----|----|----|----|-----|
| 60 | 51 | 35 | 32 | 23  |
| 57 | 49 | 34 | 31 | 20  |
| 52 | 48 | 33 | 30 | 20  |
| 52 | 47 | 33 | 30 | 8.9 |

A sample of unguentum zinci oxidi was found to be composed of 10.5 per cent. of oxide of zinc mixed with plain lard. The Pharmacopœia demands 20 per cent. of the zinc salt to be mixed with benzoated lard.

*Vinum Album*: 12 samples, all inferior, as shown by the following figures :—

| ALCOHOL (BY WEIGHT). | Extract. | ALCOHOL (BY WEIGHT). | Extract. |
|----------------------|----------|----------------------|----------|
| 19.17, . . . . .     | 4.70     | 15.17, . . . . .     | 5.90     |
| 18.85, . . . . .     | 5.14     | 15.06, . . . . .     | 6.00     |
| 17.15, . . . . .     | 4.14     | 14.64, . . . . .     | 7.29     |
| 17.00, . . . . .     | 6.46     | 13.54, . . . . .     | 7.96     |
| 15.47, . . . . .     | 6.00     | 13.41, . . . . .     | 7.00     |
| 15.45, . . . . .     | 7.50     | 13.03, . . . . .     | 6.00     |

The Pharmacopœia demands 10 to 14 per cent. of alcohol and 1.5 to 3 per cent. of solid extract. The high extract was due chiefly to added sugar.

*Vinum Rubrum*: 12 samples, all inferior, as follows :—

| ALCOHOL (BY WEIGHT). | Extract. | ALCOHOL (BY WEIGHT). | Extract. |
|----------------------|----------|----------------------|----------|
| 18.08, . . . . .     | 11.44    | 15.00, . . . . .     | 12.20    |
| 17.00, . . . . .     | 10.15    | 14.91, . . . . .     | 13.76    |
| 16.92, . . . . .     | 11.49    | 14.09, . . . . .     | 15.03    |
| 16.62, . . . . .     | 13.59    | 13.69, . . . . .     | 10.42    |
| 16.15, . . . . .     | 13.04    | 12.62, . . . . .     | 10.50    |
| 15.17, . . . . .     | 10.09    | 11.31, . . . . .     | 11.99    |

The Pharmacopœia demands 10 to 14 per cent. of alcohol and 1.6 to 3.5 per cent. of solid extract. As a rule port wine contains a large amount of added sugar.

Several samples of Mme. Ruppert's face bleach have been examined and all were found to contain corrosive sublimate to the extent of about 27 grains per 8 ounce bottle. The bottles were provided with the poison labels required by statute, but they were pasted on the bottoms of the bottles, where they are fairly certain to escape the notice of the average purchaser.

A sample of "Perry's Freckle Lotion" was found to contain 39 grains of the same poison per 8 ounce bottle.

A "Recamier Balm" was found to consist essentially of zinc oxide suspended in water with a trace of corrosive sublimate.

An "Excelsior Hair Tonic" consisted essentially of a bay rum containing quinine.

A sample of "Pulmonine" was found to contain 16 per cent. of alcohol by volume.

A "Coca-Kola" preparation contained caffein, cocain, sugar and tartaric acid.

"Hunyadi Granules" were found to consist essentially of tartaric acid and bicarbonate of soda.

"Vichi Granules" were of the same composition.

*Summary.*

Respectfully submitted,

CHARLES P. WORCESTER.

## PROFESSOR GOESSMANN'S REPORT.

---

The whole number of samples of milk obtained and examined in the four western counties during the year was 245, of which number 60, or 24.5 per cent., proved to be below the standard.

It would be fair, however, to exclude from this number 12 samples which were obtained in West Deerfield from suspected producers, of which number 11 were found to be below the standard. Three of this number were taken from one dairy, and the results of analysis showed the following figures: 8.69, 7.44 and 6.66 per cent. of total solids respectively, the latter being the lowest taken during the year, and representing about 50 per cent. of added water. This man was promptly convicted and fined.

With these exceptions the percentage of adulterated samples in milk taken under the usual conditions of sale was 21, or a trifle less than that of 1894.

The ratio of adulteration for the past ten years shows a fairly uniform quality, the figures being as follows:—

| YEAR.           | Per Cent. of<br>Adulteration. | YEAR.           | Per Cent. of<br>Adulteration. |
|-----------------|-------------------------------|-----------------|-------------------------------|
| 1886, . . . . . | 20.0                          | 1891, . . . . . | 18.4                          |
| 1887, . . . . . | 10.5                          | 1892, . . . . . | 19.8                          |
| 1888, . . . . . | 15.7                          | 1893, . . . . . | 20.3                          |
| 1889, . . . . . | 17.7                          | 1894, . . . . . | 21.3                          |
| 1890, . . . . . | 22.6                          | 1895, . . . . . | 21.0                          |

Mean ratio, ten years, 18.9 per cent.

These figures are the result of examination of 2,407 samples, of which 456 were below standard.

The following summary embraces the samples of milk obtained during the year in cities and towns west of Worcester County.

The results of analyses were as follows :—

|                              |   |   |   |   |   |   |   |   |      |
|------------------------------|---|---|---|---|---|---|---|---|------|

# REPORT

UPON THE

## PRODUCTION AND USE OF ANTITOXIN.

---

---

[687]

## REPORT UPON THE PRODUCTION AND USE OF ANTITOXIN.

---

In the last annual report of the State Board of Health (p. cvii) brief reference was made to the work of the Board which had been undertaken for the purpose of providing a supply of antitoxin for general use in reducing as far as possible the fatality from diphtheria in Massachusetts. The saving of human life, which had been claimed by Dr. Roux in his report upon this subject at the International Congress of Hygiene at Buda Pesth in 1894, and the similar results elsewhere attained on both sides of the Atlantic, were apparently demonstrated in so convincing a manner as to warrant the adoption of antitoxin both as a therapeutic and preventive remedy for general use. Hence the Board, acting under the provisions of the statutes requiring it to "take cognizance of the interests of health and life among the citizens of the Commonwealth," and believing it possible to reduce the fatality and consequently the death rate from diphtheria, not only by recommending the use of this measure for the purpose, but also by providing the material for such use, established in October, 1894, a laboratory for the production of antitoxin, and appointed Dr. J. L. Goodale of Cambridge to superintend the work of its preparation. The scope of this laboratory was soon afterward enlarged, so as to embrace general bacteriological work. Dr. Goodale entered upon the work with enthusiasm, and the successful operation which was thus secured was largely due to his earnest devotion to this work. Since, however, it soon became necessary to provide for additional bacteriological work on a larger scale, Dr. Theobald Smith, chief of the Division of Pathology of the Bureau of Animal Industry at Washington, D. C., was appointed pathologist of the Board, to take charge of this department.

After the necessary preliminary steps had been taken toward securing a continuous supply of antitoxin (providing the stables, purchasing the horses, preparing and injecting the toxine, etc.), the first quantity of antitoxin of a sufficient strength for use in the preventive treatment of diphtheria was offered for distribution in March, 1895, and the following circular was then published and distributed to boards of health throughout the State:—

## COMMONWEALTH OF MASSACHUSETTS.

## DIPHThERIA ANTITOXIN.

*[A Circular of the State Board of Health.]*

STATE HOUSE, BOSTON, March 25, 1895.

The investigations of Behring and Roux with reference to the value of serum-therapy in the treatment of diphtheria, and the later experience of its use in diminishing the mortality from this disease, are widely known and fully understood.

The State Board of Health, in accordance with its organic purpose as defined in the statutes, having in view the "interests of health and life among the citizens of the Commonwealth," and recognizing the value to the people of any agent which will measurably prevent the ravages of a disease capable of destroying more than a thousand of lives annually in Massachusetts and of causing suffering which cannot be expressed numerically, has prepared a supply of antitoxin, for the benefit, primarily, of such communities in this State as find it difficult or impracticable for any reason to supply themselves with the new agent from reliable sources.

Great care has been exercised in the preparation of this supply to fulfil the most exacting technical requirements for obtaining a pure and trustworthy product, and the tests of its strength have shown satisfactory results.

The Board does not propose to offer it for sale, but its gratuitous distribution will be under strict conditions designed to prevent abuse and waste and to obtain the most beneficial fruits. Each bottle is marked with a number and the date of the preparation of its contents. No antitoxin will be issued except upon a pledge that a full statement of the observed effects of its use will be returned to the Board at the termination of the case. In all instances possible a bacterial diagnosis will be insisted upon. The Board desires to emphasize the importance of using such appliances only as are adapted to the proper administration of the remedy, of remembering that experience has demonstrated that antitoxin is most useful in the earliest stages of a diphtheritic attack, and of realizing that trained medical skill is required to administer it successfully.

A blank form for the report and a detailed statement of instructions as to methods will accompany each bottle of the antitoxin serum.

For the needs of persons living within twenty-five miles of Boston, it will be required, for the present, that personal application at the office of the Board shall be made by the attending physician in the diphtheria case, or by some person authorized by him. For the convenience of more distant parts of the State, local agencies at public hospitals or municipal health offices will probably be established by the Board in accessible centres.

The office of the Board (Room 141, State House Extension) is open each week-day, except Saturday, from 9 A.M. to 5 P.M., and on Saturday from 9 A.M. to 2 P.M.

SAM'L W. ABBOTT, *Secretary.*

as a matter of convenience, therefore, the time embraced in this report is made to include the full year ending with March 31, 1896, as the general distribution of antitoxin by the Board may be considered as beginning about one year earlier than that date, although no vials were issued during the last week of March, 1895.

Diphtheria usually prevails with considerable severity in the spring months, but not so severely as in winter; and, since the lack of the same character proposed for the city of Boston was not in operation, the demand for antitoxin which came, not only from cities and towns but also from the newly equipped contagious disease hospital of Boston, for several weeks required all that the Board could supply. With the exception, however, of a few days in midsummer, it was enabled to supply all that was demanded.

The compiler recognizes, at the outset, the extreme difficulties attending the analysis of the results of the use of antitoxin, and therefore availed himself of the recognized authorities upon the subject, and has followed their methods as closely as possible in preparing these results.

Rarely any subject in medicine, requiring careful analysis, presents so great a multiplicity of limiting conditions and circumstances.

For example, the diagnosis of the disease, the age and sex of the patient, the severity of the attack, the time elapsing before the employment of antitoxin, the previous condition of the patient, the quantity and strength of the serum employed, the existence of complications and of surgical operations performed upon the patient, each and all of these conditions affect the result, and some of them to a very important degree.

In Dr. Welch's admirable monograph on the "Treatment of diphtheria by antitoxin" a summary is presented which gives the results of the use of antitoxin in 7,166 cases of diphtheria. This consists of the experience of 82 observers, widely separated, in different parts of the world, including France, Germany, Austria, Prussia, Switzerland, England and America. The deaths were 9, or 17.3 per cent. of the whole number of cases. It was stated, from observations recorded by these same authorities, that the mean fatality in the same places and under similar conditions, before the introduction of antitoxin, was 42.1 per cent. The foregoing figures are very largely quoted from hospital practice wherein the fatality is invariably and for obvious reasons greater than that which occurs in general private practice.

The following figures give the fatality from diphtheria and croup in general practice in England and in Massachusetts, and, being the results of observation in over 84,000 cases, may be taken as fairly correct.

That of England for the five years (1890-94) was 24.4 per cent., being the ratio of 17,318 deaths to 71,003 reported cases; and that of Massachusetts for 1891-94 was 28.3 per cent., being the ratio of 3,768 deaths to 13,332 notified cases.

The actual fatality in Massachusetts was probably slightly less than 28.3, in consequence of the fact that the registered deaths from diphtheria may be regarded as nearly correct, while the number of reported cases must be regarded as less than the actual number, on account of failure or neglect to report in some instances, especially in small towns, where no well-organized boards of health exist.

The claim has been made that the decrease in fatality in diphtheria is not due to the use of antitoxin, but to improved modes of diagnosis, by means of bacterial cultures. On the other hand, it is also true that before the introduction of more accurate means of diagnosis it was a quite common practice with some physicians to report all cases of sore throat as diphtheria, so that these two facts must be considered together.

From all the evidence that we can obtain from recorded observations, we are inclined to believe that 25 per cent. should be considered as being about the average fatality for diphtheria in Massachusetts during the five years previous to the introduction of antitoxin. During the severe epidemic years from 1875 to 1882, it is probable that the fatality was somewhat greater.

The fatality in hospital practice may be considered as at least 50 per cent. greater than that of general practice, since mild cases do not generally reach the hospital, and many of those who are sent for hospital treatment are beyond all prospect of recovery at the time of admission.

The limited character of this report, that is to say, the defect due to the fact that a very considerable portion of the antitoxin issued is unaccounted for by any returns from those who used it, is due to several causes. First, the distribution of the material over a large extent of territory (in some instances one hundred and fifty miles or more from the base of supply); second, its use in many instances in small towns in which the physicians were unused to the work of making returns; third, about two hundred packages were

or immunizing; fourth, a small allowance must be made for  
 ges of bottles and for packages remaining unused on deposit  
 ards of health.

first bottles of serum, issued near the close of March, 1895,  
 ed twenty cubic centimeters of serum each, and for several  
 this quantity was put into each vial; but, as the strength of  
 um was increased, the size of the receptacle was diminished,  
 fifteen cubic centimeters and finally to ten cubic centimeters,  
 er size being at present employed exclusively, for the pur-  
 f containing the quantity of serum most convenient for im-  
 e use, since it is essential to its proper employment that no  
 of the contents should be reserved for future use after a  
 has once been opened, unless such reserved portion be used  
 a few hours (twenty-four hours at the extreme limit) after-

total amount of antitoxin serum issued by the Board during  
 ar ending March 31, 1896, was 1,724 bottles, containing in  
 ut 30,000 cubic centimeters of serum, the strength of which  
 from sixty to one hundred units in each cubic centimeter.  
 serum was distributed to the cities and towns as follows:—

| Worcester, . . . . . | 1                 |                             |                    |

It was distributed to the following hospitals, in accordance with demand from them :—

In Boston, the City Hospital for Contagious Diseases, the Children's Hospital, the Massachusetts General Hospital; in Cambridge, the Cambridge Hospital (contagious ward); in Newton, to the Newton Hospital; in Lynn, to the Lynn Hospital for Contagious Diseases; in Waltham, to the Waltham Hospital; in Brookline, to the Brookline Hospital for Contagious Diseases; in Pittsfield, to the House of Mercy; in Westborough, to the Lyman School for Boys.

The board of health of Worcester and the House of Mercy at Pittsfield lent their efficient co-operation by acting as distributing centres for the smaller neighboring towns.

In order that the results of the use of the serum issued by the Board might be known as fully as possible, a blank form was prepared and issued with each package of antitoxin, of which the following is a copy :—

MASSACHUSETTS STATE BOARD OF HEALTH.

BLANK FOR RECORDING TREATMENT WITH DIPHTHERIA ANTITOXIN.

Name of attending physician,

Address,

Name of patient,

Address,

Age,

Results of bacteriological examination,

Physical condition of patient previous to present illness,

Date when symptoms first appeared,

Condition at time of first injection of antitoxin (underline symptoms mentioned below which are present).

- LOCAL.** { *Nose*: coryza, purulent discharge, false membrane.  
*Pharynx*: state distribution of false membrane,  
*Larynx*: hoarseness, cough, dyspnoea, stenosis.  
*Cervical glands*: changes,  
*General appearance*: degree of prostration, etc.,  
*Lungs*: note character and extent of involvement,  
**GENERAL.** { *Heart*: note strength of action and any abnormalities,  
*Kidneys*: give analysis of urine,  
 Other complications,

The subsequent history is to be noted on the chart on the next page.

This blank should be properly filled and returned to the office of the Board, Room 142, State House, in each and every case in which antitoxin furnished by the Board is employed.

The importance of returning these blanks properly filled with the items relative to each case does not appear to have been fully appreciated by the physicians who have used the antitoxin in different parts of the State. Our knowledge of the effect of any new therapeutic agent must be the result of observation, and it is very desirable that the observations of physicians in private practice should be fully recorded, since very much of the published results from the use of antitoxin are derived from hospital reports. Hence the Board would respectfully urge all physicians who are in the habit of obtaining the antitoxin prepared and furnished by the Board to report upon the same in as full a manner as possible.

The whole number of individual reports received by the Board from all sources for the year ending March 31, 1896, was 562. It is impossible to state the exact number treated with the antitoxin furnished by the Board during the time stated. It is probably not far from 1,000.

In order to form a just estimate of the value of this agent from the experiences recorded, it will be necessary to classify the returns,

and to separate those where a bacterial diagnosis was made by culture from those where no such examination was made. Of the former there were 289 returns and of the latter there were 273.

*Cases in which a Bacterial Examination was made.*—It is desirable to divide this class into two groups,—those in which the diagnosis was positive and those in which it was negative. There were 262 cases in which the diagnosis was positive, as shown by cultures taken from the throat, and of this number 36 died, or 13.7 per cent. of the whole number of positive cases.

*Sex.*—The number of males was 125, and the deaths of these were 18, or 14.4 per cent. The number of females was 135, and the deaths of these were 17, or 12.6 per cent. The sex of two was not stated.

*Ages.*—By ages the numbers and the deaths were as follows:—

| AGE PERIODS.                 | Cases. | Deaths. | Fatality<br>(Per Cent.). |
|------------------------------|--------|---------|--------------------------|
| From 0 to 2 years, . . . . . | 30     | 9       | 30.0                     |
| " 2 to 5 " . . . . .         | 71     | 16      | 22.5                     |
| " 5 to 10 " . . . . .        | 91     | 9       | 9.9                      |
| Over 10 years, . . . . .     | 67     | 2       | 3.0                      |
| Age unknown, . . . . .       | 8      | 0       | 0.0                      |
| Totals, . . . . .            | 262    | 36      | —                        |
| Mean, . . . . .              | —      | —       | 13.7                     |

*Day of Illness when Antitoxin was first administered.*

|                                 |                                   |
|---------------------------------|-----------------------------------|
| Fatality, . . . . . 1st day, 0. | Fatality, . . . . . 5th day, 22.2 |
| " . . . . . 2d " 9.7            | " . . . . . 6th " 20.0            |
| " . . . . . 3d " 8.7            | " . . . . . 7th " 33.3            |
| " . . . . . 4th " 15.4          |                                   |

In many instances the day of administration was not stated. The foregoing table relates only to those cases in which the day of illness is noted on which the antitoxin was used.

*Negative Cases.*—There were also 27 cases in which the bacterial examination gave either a negative or a doubtful result (23 negative and 4 doubtful), and the deaths among these were 5, or 18.5 per cent.

The fatality of positive cases treated in hospitals was as follows: cases, 85; deaths, 15, = 17.6 per cent.; in private practice, cases, 10; deaths, 21, = 11.9 per cent.

*Cases in which no Bacterial Examination was made.*—In the second series, in which no bacterial examination was made, the total number of cases in which antitoxin was reported as having been employed was 273, and the number of deaths recorded was 32, or 11.7 per cent.

*Sex.*—The number of males treated was 123, and the deaths of these were 14, or 11.4 per cent. The number of females was 143, and the deaths of these were 17, or 11.9 per cent.

*Ages.*—Of children under 2 years of age, 10 were treated, and the deaths of these were 5, or 50 per cent. Of children from 2 to 5 years of age there were 71 cases and 10 deaths, or 14.1 per cent. Of children from 5 to 10 years old there were 104, with 13 deaths, or 12.5 per cent. Of persons over 10 years of age there were 75, with 2 deaths, a fatality of 2.7 per cent. Of persons of unknown age there were 13, with 2 deaths.

The following record presents a brief statement of each of the fatal cases which occurred among those which had been determined by bacterial examination to be cases of diphtheria:—

#### DEATHS.

##### *Private Practice.*

1. Male, one year (February, 1896). Marked prostration, membrane general in pharynx. Improvement for ten days, followed by paralysis of throat, hoarseness, cough and dyspnoea, considerable swelling of glands of neck, marked prostration. Ten cubic centimeters of antitoxin, time not stated.

2. Male, three years (January, 1896). Treatment begun fourth day of illness. Face flushed, membrane on right tonsil and in nares; detaching and throat clear on sixth day; hoarseness, cough and dyspnoea; glands of neck swollen on right side; heart and urine normal. Death on seventh day. Antitoxin given on fourth and fifth days, 15 cubic centimeters at each time.

3. Male, one year (November, 1895). Treatment begun fourth day of illness. Membrane slight, on both tonsils. Slight improvement and increase of membrane; cough and dyspnoea; glands of neck slightly enlarged; heart weak, rapid and irregular. Antitoxin, 10 cubic centimeters on fourth day and 10 cubic centimeters on sixth day.

4. Male, one year, eight months (December, 1895). Moderate prostration, no membrane visible; grows worse; dyspnoea; glands not enlarged; pulse rapid; moderate prostration. Intubation, second day; convulsions on sixth day and death same day. Antitoxin, 10 cubic centimeters on second day and 20 cubic centimeters third day.

5. Female, one year, four months (Dec. 2, 1895). Treatment begun fourth day of illness. General condition bad; membrane on both tonsils; purulent discharge. Throat clear on third day; hoarseness, cough, dyspnoea and stenosis; glands enlarged; pulse weak. Intubation on fifth day; death during intubation. Antitoxin, 8 cubic centimeters on fourth day.

6. Male, twenty-four years (Oct. 16, 1895). Treatment begun third day of illness. Great cyanosis and prostration; membrane on both tonsils and right portion of pharynx; hoarseness, cough and dyspnoea; pulse weak, 100-140, temperature, 100-102; considerable prostration. Antitoxin, third day, morning, 12 cubic centimeters; afternoon, 8 cubic centimeters. Death, fifth day.

7. Male, five years, six months (Oct. 7, 1895). Membrane over tonsils and arches; glands enlarged; pulse irregular and intermittent; paralysis of heart; death. Eruption on whole body, like scarlet fever. Antitoxin, 15 cubic centimeters (day not stated), 5 cubic centimeters on following day.

8. Female, four years (Sept. 21, 1895). Treatment begun second day of illness. Prostration marked; membrane on both tonsils and half arches; glands much enlarged; pulse very weak; urine albuminous; delirium and death. Antitoxin on second day, 15 cubic centimeters. Extravasated blood spots on body after injection.

9. Female, eight years (Sept. 27, 1895). Toxæmia from outset; membrane on tonsils, uvula and posterior pharynx; profuse nasal discharge; marked swelling of glands; pulse rapid and weak. Death on fourth day. Antitoxin, 30 cubic centimeters.

10. Male, nine months (Sept. 7, 1895). Treatment begun fourth day of illness. Temperature, 103-104; pulse, 160-175. Extreme septic appearance; prostration; no membrane; coryza; increasing nasal discharge; dyspnoea; glands very much enlarged on both sides. Antitoxin, 10 cubic centimeters on fourth day.

11. Male, nine months (June 25, 1895). Treatment begun fifth day of illness. Temperature, 101.5-102.1; pulse, 140-170; marked prostration; hoarseness, cough and dyspnoea; glands swollen and tender; heart weak and rapid. Antitoxin, 12 cubic centimeters on fifth day.

12. Male, nine years (Sept. 4, 1895). Treatment begun second day of illness. Temperature, 99-101; pulse, 100-120. Slight prostration; membrane on tonsils, uvula and posterior wall of pharynx; not separated; hoarseness and dyspnoea; glands enlarged; heart normal; urine mal. Antitoxin, 10 cubic centimeters on second day.

3. Male, three years. Treatment begun April 7, 1895, sixth day of illness. Temperature, 99.4-100.5; pulse, 104-135; drowsy; no membrane; coryza on sixth day, less on seventh day; glands enlarged; bronchopneumonia. Antitoxin, 20 cubic centimeters sixth day, 20 cubic centimeters seventh day.

14. Female, two years (May 20, 1895). Treatment begun fourth day of illness. Temperature, 102–104; pulse, 160; moderate prostration; drowsy; membrane covering tonsils and uvula, separating on fifth day; glands enlarged and indurated; urine scanty and albuminous. Antitoxin, 15 cubic centimeters fourth day, 10 cubic centimeters fifth day and 5 cubic centimeters sixth day.

15. Female, three years (treatment begun May 25, 1895, seventh day of illness). Temperature, 101; pulse, 112–116; marked prostration; membrane generally over tonsils and pharynx; glands not swollen; pulse weak, but regular; urine very albuminous; specific gravity, 1032. Antitoxin, 15 cubic centimeters on seventh day.

16. Male, three and one-half years (treatment begun May 25, 1895, fourth day of illness). Temperature, 99–100; pulse, 132–152; slight prostration, increasing on fifth day; membrane over tonsils, palate and uvula, separating on fifth day; hoarseness and slight dyspnoea; glands on right side enlarged; pulse rapid; prostration and dyspnoea increasing till death. Antitoxin, 15 cubic centimeters on fourth day, A.M., 10 cubic centimeters P.M. and 10 cubic centimeters on fifth day, A.M.

17. Male, seven years (treatment begun April 25, 1895, fifth day of illness). Considerable prostration; hoarseness; cough; dyspnoea; stenosis; urine albuminous; intubation; complicated with scarlet fever and measles. Died at 9.15 P.M., fifth day. Antitoxin, 20 cubic centimeters on fifth day.

18. Female, three years (treatment begun May 1, 1895). Slight prostration; membrane on tonsils, disappearing May 18; glands enlarged; complicated with scarlet fever. Died May 18. Antitoxin 20 cubic centimeters May 1, 20 cubic centimeters May 18.

#### *Cambridge Hospital.*

19. Female, one year, six months (admitted Aug. 14, 1895, fifth day of illness). Temperature, 101.6; pulse, 136, on fifth day. Considerable toxæmia; membrane over both tonsils, separating; hoarseness; glands enlarged and hard; heat normal; general paralysis and death September 18. Antitoxin, 12 cubic centimeters on fifth day and 12 cubic centimeters on sixth day. Negative culture on August 31, followed by rash all over body, gradually disappearing.

#### *Boston City Hospital.*

20. Sex not stated, four years (admitted June 1, 1895). Treatment begun third day of illness. General condition weak; membrane on both tonsils, separating on fifth day; glands swollen; heart weak; child vomits everything. Antitoxin, 10 cubic centimeters on third day, 10 cubic centimeters on fourth day.

21. Female, three and one-half years (admitted May 1, 1895). Treatment begun fourth day of illness. Temperature, 99; pulse, 134; slight prostration; membrane on both tonsils and in pharynx; throat nearly clear on seventh day; tonsils slightly enlarged; heart rapid; urine albuminous; bronchitis. Antitoxin, 15 cubic centimeters on fourth day. Removed from another hospital without consent of physician.

22. Female, four years (admitted June 11, 1895). Treatment late. Temperature, 103; pulse, 120; general condition bad; membrane on uvula and tonsils, separating; dyspnoea; glands not swollen; heart weak. Antitoxin, 20 cubic centimeters (1-50,000). Injection delayed on account of objections of family. Death from suffocation four and one-half hours after injection.

23. Female, nine years (admitted July 12, 1895). Treatment begun second day of illness. Temperature, 101.2-103; pulse, 60-150; general condition good; some prostration; membrane on left tonsil and soft palate; glands of neck swollen; pulse regular, rapid; urine normal; thin, glairy discharge from mouth. Antitoxin, 12 cubic centimeters on second day, 12 cubic centimeters on second day, 13 cubic centimeters on third day.

24. Female, two years (admitted May 3, 1895, fifth day of illness). Temperature, 102.3; pulse, 126; membrane thick on both tonsils; hoarseness and dyspnoea; glands slightly swollen; circulation poor; prostration; complicated with sepsis. Antitoxin, 20 cubic centimeters on fifth day.

25. Male, six years (admitted May 9, 1895). Temperature, 98-101; pulse, 100-132; great prostration; membrane thick on tonsils, uvula, pharynx and soft palate, separating third day after admission to hospital; hoarseness and dyspnoea; glands enlarged; pulse weak. Antitoxin, 20 cubic centimeters May 9, A.M., 20 cubic centimeters May 9, P.M., 20 cubic centimeters May 11.

26. Female, one year, six months (admitted April 26, 1895). Temperature, 99.4-104; pulse, 110-160; considerable prostration; membrane on tonsils and uvula; purulent discharge from nose; separating April 29; glands swollen; broncho-pneumonia, complicated with sepsis. Antitoxin, 15 cubic centimeters April 26, 12.5 cubic centimeters April 27.

27. Female, one year, six months (admitted April 29, 1895). Temperature, 98.4-102; pulse, 120-160; slight prostration; membrane on tonsils; no change; glands swollen; urine albuminous; sepsis May 4; extreme prostration May 3. Antitoxin, 20 cubic centimeters April 29.

28. Female, six years (admitted May 15, 1895). Temperature, 98-100.8; pulse, 68-140; extreme prostration; thick membrane over both tonsils, uvula and soft palate; purulent discharge from nose; epistaxis; no improvement; hoarseness, cough and dyspnoea; glands slightly swollen; pulse weak; heart failure May 22; complicated with scarlet fever. Antitoxin, Gibier's, May 15, 25 cubic centimeters; S. B. H., May 16, 25

cubic centimeters; S. B. H., May 17, 25 cubic centimeters; S. B. H., May 18, 25 cubic centimeters.

29. Male, three years (admitted May 15, 1895, second day of illness). No prostration; membrane in small patches on tonsils; separating; throat clear on second day; stenosis; glands not swollen; heart and urine normal; scarlet fever; pneumonia in left chest on fourth day. Antitoxin, 20 cubic centimeters second day, third day and fourth day.

30. Male, three years (admitted May 26, 1895, second day of illness). Prostration; patches on tonsils; hoarseness, cough, dyspnoea and croup; glands slightly enlarged; heart weak; tracheotomy; pneumonia. Antitoxin, 20 cubic centimeters on second day, fourth day and fifth day.

31. Male, five years (admitted May 29, 1895). Extreme prostration; membrane thick on tonsils and uvula; no change; dyspnoea; glands slightly swollen; pulse very weak and irregular; heart failure; sepsis. Antitoxin, 20 cubic centimeters, May 29 and May 30.

32. Female, five years (admitted May 24, 1895). Considerable prostration; membrane one-third over tonsils and uvula; separating May 31; glands not swollen; sepsis June 9; great prostration; great pain; delirium. Antitoxin, 20 cubic centimeters, May 24, 25, 27 and 30.

33. Male, four and one-half years (admitted April 16, 1895, third day of illness). Temperature, 98.4–102; pulse, 112–160; considerable prostration; membrane on tonsils and uvula, diminishing on fifth day; glands enlarged; broncho-pneumonia. Antitoxin, 20 cubic centimeters on third day, 20 cubic centimeters on fourth day and 20 cubic centimeters on fifth day.

34. Male, four years (admitted April 13, 1895, sixth day of illness). Temperature, 100; pulse, 120; condition very septic; membrane on tonsils and uvula; urine albuminous. Antitoxin, 20 cubic centimeters on sixth day.

35. Female, two years (admitted April 22, 1895). Temperature, 98–100.4; pulse, 100–152; condition extremely septic; membrane on tonsils and uvula; epistaxis on April 24; glands enlarged; urine slightly albuminous; extreme prostration April 25. Antitoxin, 20 cubic centimeters, April 22.

#### *Newton Hospital.*

36. Female, twenty-two years (admitted March 24, 1895, fourth day of illness). Temperature, 99.8–103.8; pulse, 100–108; marked prostration; membrane over tonsils, uvula and post-pharyngeal wall, separating on fifth day; throat clear on ninth day; hoarseness and dyspnoea; glands swollen; pulse irregular. Antitoxin, 10 cubic centimeters on fourth day, 23 cubic centimeters fifth day, 15 cubic centimeters sixth day, A.M., 23 cubic centimeters P.M., 23 cubic centimeters seventh day.

An exact statement cannot be made as to the strength of the rum used in each of the foregoing cases, but it may be said in general terms that those treated before Jan. 1, 1896, were treated with a weaker serum, 1 to 50,000, and the remainder with the stronger rum, 1 to 75,000 or 1 to 100,000.

The value of antitoxin as a therapeutic agent cannot be determined by figures alone. The varied circumstances and conflicting conditions which surround and influence any case of diphtheria are great that we are compelled to seek other sources of information than those which are purely statistical in their character.

The clinical experience of the multitude of observers, who, in hospital and in private practice, during the past two years have testified its value, must be weighed and considered in connection with the statistical facts presented.

Dr. Mason makes the following statement relative to the use of antitoxin at the Boston City Hospital in 1895:—

If we compare this death-rate from diphtheria of 11 per cent. since the introduction of antitoxin with that of a death-rate in the hospital of 40 per cent. before the introduction of antitoxin, there can be but one opinion regarding the efficacy of the remedy.

The change in the appearance of diphtheria wards since the introduction of the use of antitoxin has been very marked. In making a visit one cannot help being struck with the bright and cheerful appearance of the children.\*

One of the most noted German authorities (Baginsky) says:—

Naked figures are so little the expression of the endless variations of clinical observation, of all those fortunate and unfortunate accidental circumstances which pertain to the constitution and nutrition of the patient, and of the complications and difficulties which may bring danger in a mild attack, or lead to a successful issue in an apparently severe attack, that to the clinical observer such figures appear of little value, in comparison with the treasure-house of his accumulated experience.

One of the most convincing proofs of the value of antitoxin is mentioned by the same writer, in what he terms an *involuntary* experiment, “where, in consequence of an interruption of the use of antitoxin at a well-known hospital, in consequence of the failure of the supply, for a period of a few weeks the mortality among the diphtheria patients immediately rose again to its former height.”

---

\* Boston Medical and Surgical Journal, Feb. 13, 1896, p. 178.

The following extracts are from the returns made to the Board by physicians using the serum : —

“This case was one that, before the days of culture tests, would have been called an undoubted case of true diphtheria, and I did not feel justified in waiting for the result of the culture to be reported to me before making use of the antitoxin.”

“Child got on without any set-back whatever. I have never had a case do so well before using antitoxin.”

“No local treatment. Internally, some tincture of iron, brandy and nourishing diet. Within twelve hours after injection of antitoxin child began to improve both in general and local symptoms.”

“Improvement in twenty-four hours was remarkable.”

“I have no doubt that antitoxin treatment has done much to help save these cases.” (By physician of forty years' experience.)

“These cases, it seems to me, furnish undoubted proof of the efficacy of antitoxin. . . . The beneficial effects were almost immediate. No extension of the membrane occurred. It was being expelled on the second day, and on the fourth day the throat was clear. Improvement in the general condition was also rapid. The result is all I think could be expected or desired.”

“This case was a highly satisfactory one in the marked improvement immediately following antitoxin.”

“The case was a very severe one, and would probably have proved fatal had not the disease been arrested promptly by the use of antitoxin. Four adults concerned more or less in the care of the child were immunized each with 5 cubic centimeters antitoxin. All escaped the disease.” (Physician of thirty years' experience.)

“In this case the disease seemed to have been arrested by the antitoxin.”

“This is my first experience in the use of antitoxin. The result is exceedingly gratifying to me and to the parents. The change in the appearance of the fauces was very apparent six hours afterward. After the second injection the membrane cleared off as I have never seen it before, and the patient's symptoms disappeared with a rapidity to which I am entirely unaccustomed. I ascribe this remarkable change to the use of the serum.”

“I consider that the use of antitoxin in this case was not only beneficial but absolutely the only curative agent.”

“I have been in the habit of seeing such cases die. I think the favorable result may honestly be attributed to the use of antitoxin.”

“Sixteen others, of all ages, living in the same house, were immunized; none of them had diphtheria.”

"Child recovered. This was one of those cases that usually proves fatal in about twenty-four hours under the old treatment."

"Action of antitoxin marvellous."

"My cases have fortunately done well, and it seems to me to be due to the prompt use of the antitoxin." (A physician of thirty years' practice.)

"In this family there occurred seven cases of diphtheria. I am satisfied that without antitoxin I should have lost four of them."

"This patient began to improve after using antitoxin."

"Since last December I have treated thirty-two cases of true diphtheria; the first eight without antitoxin, of which four died; and the remaining twenty-four with antitoxin, with only one death. At least half of the last series of cases were as severe as the first eight."

"A physician of more years in experience than myself, who saw the patient the day of the injection, considered that the case was hopeless without the antitoxin."

"Antitoxin saved this child's life."

"Rapid improvement from time of injection."

The following conclusions and recommendations are selected from the work of Baginsky, already quoted, in consequence of their practical value:—

3. The antitoxin has proved, from the first, an efficient and the best means for the prevention of diphtheria.

4. The technique of injection corresponds with that of ordinary subcutaneous injections, and in like manner presupposes the strict employment of aseptic methods.

5. (a) The serum acts most successfully the sooner it is applied after first appearance of illness. A combination of its use with the ordinary topical local treatment of diphtheria is entirely rational, and is recommended for practical use. By this combined method we have succeeded in diminishing the fatality to one-third of its former rate.

b) The dose depends on the early or late period of its employment, the severity of illness and the age of the patient. It varies from 600 to 4,000 toxin units. An advantage is gained by using the whole dose at the outset. Nevertheless, in stubborn cases an increased dose may be given.

The effect of the remedy is manifest in the limitation and arrest of local processes; also in the rapid dissolution and removal of the disintegrating product and in the general improvement, which generally shows itself as a lessening of febrile reaction.

The remedy appears most efficient in non-septic cases of diphtheria; nevertheless, cases in which mixed infectious and septic diphtheria are concerned are favorably affected by its use. A larger dose is necessary in such cases.

8. The use of the antitoxin is followed by no serious results or illness. The eruptions which often follow its use, although attended with swollen glands or affections of the joints, are wholly without danger. Kidney or heart symptoms do not result from its use.

The following list presents the names of the cities and towns from which detailed reports were received relative to the use of antitoxin, with the number from each town and the number of physicians reporting in each:—

*List of Cities and Towns from which Reports have been received Relative to the Use of Antitoxin in the Treatment of Diphtheria, with the Number of Reports from Each and the Number of Physicians reporting in Each.*

| PLACES.                    | Number Physicians reporting. | Cases in which Cultures made. | No Cultures. | PLACES.                      | Number Physicians reporting. | Cases in which Cultures made. | No Cultures. |

soon as the discovery of the new remedy, *diphtheria anti-* was made known to the world, and the methods of its prepara- were also made public, several establishments both in Europe America undertook its manufacture, and different brands of in were offered for sale. In order, therefore, that the of the different preparations of so important a remedy might rmined for the benefit of local boards of health, hospitals and ans in active practice throughout the State, the State Board lth, acting under the provisions of the food and drug act of directed an examination of the preparations in the market to le, and published the result in a circular, of which the follow- copy :—

STATE HOUSE, BOSTON, April 6, 1896.

r authority of the statutes relating to food and drug inspection, the oard of Health has examined such samples of antitoxin as are for sale in Massachusetts, with the following results :—

n No. 2, Behring. Bottle containing 10 cubic centimeters of of an advertised strength of 1,000 units. The test showed that the as up to the standard.

a of Parke, Davis & Co. Bottle guaranteed to contain 10 cubic ters, of a total strength of 1,000 units. The test showed that the as up to the standard.

Serum No. 2 of Mulford & Co. The label states that the bottle contains 10 cubic centimeters, of a total strength of 1,000 units. The test confirmed the statement, and showed the serum to be up to the guaranteed strength.

Serum of the Pasteur Institute of Paris, France (Roux). The circular states that the serum is at least 1 to 50,000 in strength. As this is considered equivalent to Behring's serum No. 1, the test was carried out with this strength in view. It was, however, found to be weaker than this. A second test showed that the 10 cubic centimeters of serum contained a total of 500 antitoxic units, instead of 600 units.

Gibier's Diphtheria Antitoxin, New York. The label states that the bottle contains 25 cubic centimeters, of a total strength of 2,500 units. The test showed that the serum was far below this in strength. In a second test it was determined that the bottle contained from 625 to 750 units, instead of 2,500, as advertised. The strength of this serum is thus a trifle below one-half of that of Behring's serum No. 1.\*

THE STATE BOARD OF HEALTH.

Copies of the foregoing circular were distributed generally among physicians and boards of health throughout the State.

---

\* Ten cubic centimeters of Behring's serum No. 1 contain 600 units.

## STATISTICAL SUMMARIES OF DISEASE AND MORTALITY.

---

the last report of the Board, the statistical material collected by the Board was published together under the head of "Statistical Summaries of Disease and Mortality." These summaries comprise statistics obtained from the authorities of cities and towns, and partly voluntary and partly the result of legal requirements. They are as follows:—

*The Weekly Mortality Returns.*—These consist of the reports of deaths, which are made up weekly and are sent to the office of the State Board by the registration officials of cities and towns. They are partly voluntary, and serve principally to show the seasonal prevalence of the chief infectious diseases, and the mortality of children under five years old in weekly periods. This series of statistics has been continued by the Board for at least twenty years, and has been published as a summary for thirteen years.

*The Reports of Certain Infectious Diseases,—Diphtheria, Croup, Scarlet Fever, Typhoid Fever and Measles.*—These are obtained from the annual reports of local boards of health for the year ending, which are forwarded to the State Board from cities and towns. By comparing the numbers of reported cases with the reported deaths, the mean fatality of each disease in the places from which the reports are made is obtained with a reasonable degree of accuracy.

*Reports of Cities and Towns, made under the Provisions of Chapter 302 of the Acts of 1893.*—By this act each local board of health is required to report to the State Board every case of "disease dangerous to the public health" which is reported to the local board. A digest of these reports is presented in the following summary (No. III.).

*Reports made under the provisions of Chapter 218 of the Acts of 1894.*—The full reports of deaths occurring in each city and town having over 5,000 inhabitants comprise another series of summaries, which are summarized in No. IV. These reports are made in accordance with the requirements of the following statute:—

### [ACTS OF 1894, CHAPTER 218, SECTION 3.]

In each city and town having a population of more than five thousand inhabitants, as determined by the last census, at least one member of said board shall be a physician, and the board shall send an annual report of deaths in such town to the State Board of Health. The form of such reports shall be prescribed and furnished by the State Board of Health.

## I.

SUMMARY OF THE WEEKLY MORTALITY RETURNS FROM  
CITIES AND TOWNS.

The following summary comprises the returns of deaths which are reported to the State Board of Health at the close of each week by such registration officials of cities and towns as comply with the request of the State Board of Health for this information. The data thus collected are entirely obtained from voluntary sources, and the results are compiled at the office of the board each week for publication in a bulletin which is distributed to the registering officers of the cities and towns. The facility of distributing this bulletin has been recently increased in consequence of a change in the postal laws, which admits the bulletin to the mails at a diminished rate of postage. It is also a useful medium for the publication of such information as it may become desirable to issue at more frequent intervals than is possible in the annual reports of the Board. The value of the weekly mortality returns consists very largely in the fact that they constitute a continuous history of the prevalence of the principal infectious diseases throughout the State, so far as can be learned from the mortality which they cause.

In connection with the results of the information obtained as a consequence of the enactment of chapter 302 of the Acts of 1893, these weekly mortality reports furnish to the Board an important index of the health of the people, as influenced by the prevalence of epidemic diseases at different seasons of the year.

The estimated mean population contributing to these returns during the year 1895 was about 1,495,000, or about three-fifths of the total population.

the data embraced in this summary are the following : —

Average height of barometer for each week.

Mean maximum temperature.

Mean minimum temperature.

Rainfall expressed in inches.

Humidity.

Total deaths reported for each week.

Deaths of children under five years.

Deaths from infectious diseases.

Deaths from consumption.

Deaths from acute lung diseases.

Deaths from typhoid fever.

Deaths from diarrhoeal diseases.

Deaths from scarlet fever.

Deaths from measles.

Deaths from diphtheria and croup.

Deaths from puerperal fever.

Deaths from whooping-cough.

Deaths from malarial fever.

Deaths from small-pox.

Deaths from erysipelas.

The following table presents a summary of the statistics compiled from the weekly mortality returns : —

## TOTAL DEATHS.

The whole number of deaths reported for the year 1895 from the cities and towns contributing to these reports was 28,978, and the average number per week was 557. The greatest number of deaths reported in a single week was 800, in the week ending March 2, and the least number was 368, in the week ending June 29. The weekly average number of deaths reported for each month was:—

|                     |     |                      |     |
|---------------------|-----|----------------------|-----|
| January, . . . . .  | 529 | July, . . . . .      | 515 |
| February, . . . . . | 658 | August, . . . . .    | 617 |
| March, . . . . .    | 665 | September, . . . . . | 567 |
| April, . . . . .    | 571 | October, . . . . .   | 542 |
| May, . . . . .      | 538 | November, . . . . .  | 518 |
| June, . . . . .     | 438 | December, . . . . .  | 535 |

The months in which the greatest mortality per week was reported were February, March and August, and those in which there was the least reported mortality were June, July and November.

The percentages of mortality in each of the four quarters of the year were as follows:—

|                           | DEATHS AT ALL AGES. |              | DEATHS UNDER FIVE YEARS. |              |
|---------------------------|---------------------|--------------|--------------------------|--------------|
|                           | Numbers.            | Percentages. | Numbers.                 | Percentages. |
| First quarter, . . . . .  | 8,080               | 27.88        | 2,376                    | 23.49        |
| Second quarter, . . . . . | 6,629               | 22.88        | 1,937                    | 19.15        |
| Third quarter, . . . . .  | 7,410               | 25.57        | 3,668                    | 36.27        |
| Fourth quarter, . . . . . | 6,859               | 23.67        | 2,133                    | 21.09        |
|                           | 28,978              | 100.00       | 10,114                   | 100.00       |

The death rate of reporting cities and towns was 19.4 per 1,000, the reporting population being 1,495,000.

## DEATHS UNDER FIVE YEARS.

The reported number of deaths of children under five years of age was 10,114, and the average weekly number was 194. The greatest number reported in one week was 392, in the week ending August

10, and the least number was 110, in the week ending June 29. The ratio of the deaths of this class to the total mortality was 34.9 per cent., which was slightly less than that of the preceding year (36.1 per cent.). The average weekly number of deaths of children under five years of age by months was as follows : —

|                     |     |                      |     |
|---------------------|-----|----------------------|-----|
| January, . . . . .  | 176 | July, . . . . .      | 229 |
| February, . . . . . | 203 | August, . . . . .    | 332 |
| March, . . . . .    | 172 | September, . . . . . | 273 |
| April, . . . . .    | 175 | October, . . . . .   | 198 |
| May, . . . . .      | 153 | November, . . . . .  | 148 |
| June, . . . . .     | 125 | December, . . . . .  | 150 |

The months having the greatest number of deaths of children under five years of age were July, August and September, and those having the least number were June, November and December.

The relation of the death rate of children under five years of age to the death rate at all ages is fully illustrated in the diagram upon page 721 of the twenty-third annual report (1891), where the mean death rate per week for a series of nine years is given. The irregularities in the death rate at all ages in different seasons of the year is shown to be very largely produced by the marked changes in the death rate of children.

#### CONSUMPTION.

The number of reported deaths from consumption was 3,119, and the weekly average was 60. The greatest number of deaths reported from this cause in a single week was 88, in the week ending February 23, and the least number was 41, in the weeks ending June 29, August 3 and August 17.

The average weekly number of reported deaths from this cause in each month was as follows : —

|                     |    |                      |    |
|---------------------|----|----------------------|----|
| January, . . . . .  | 56 | July, . . . . .      | 51 |
| February, . . . . . | 77 | August, . . . . .    | 47 |
| March, . . . . .    | 75 | September, . . . . . | 53 |
| April, . . . . .    | 64 | October, . . . . .   | 59 |
| May, . . . . .      | 60 | November, . . . . .  | 59 |
| June, . . . . .     | 62 | December, . . . . .  | 56 |

The months having the greatest number of deaths from this cause were February and March, and those having the least were July

and September. The following table presents the variations from the weekly average number of deaths from this cause for the past five years :—

|             | 1891. | 1892. | 1893. | 1894. | 1895. |              | 1891. | 1892. | 1893. | 1894. | 1895. |
|-------------|-------|-------|-------|-------|-------|--------------|-------|-------|-------|-------|-------|
| January, .  | +4    | +13   | +8    | +10   | -4    | July, .      | -4    | -3    | -7    | 0     | -9    |
| February, . | -4    | -8    | -3    | +7    | +17   | August, .    | -3    | -4    | -1    | -4    | -13   |
| March, .    | -5    | -1    | +9    | +9    | +15   | September, . | -3    | -11   | -1    | -3    | -7    |
| April, .    | +4    | +7    | +13   | -1    | +4    | October, .   | +3    | -5    | -10   | -6    | -1    |
| May, .      | +6    | 0     | +1    | -7    | 0     | November, .  | -4    | -4    | +2    | -7    | -1    |
| June, .     | -2    | -5    | -9    | -1    | +2    | December, .  | +5    | -1    | -6    | +2    | -4    |

The ratio of reported deaths from consumption to the mortality reported from all causes was 107.7 per 1,000, while that of previous years was as follows :—

|                 |       |                 |       |
|-----------------|-------|-----------------|-------|
| 1888, . . . . . | 134.2 | 1892, . . . . . | 111.3 |
| 1889, . . . . . | 125.0 | 1893, . . . . . | 106.5 |
| 1890, . . . . . | 130.0 | 1894, . . . . . | 111.8 |
| 1891, . . . . . | 116.5 | 1895, . . . . . | 107.7 |

The ratio to the reported living population in 1895 was 2.09 per 1,000.

#### ACUTE LUNG DISEASES.

The number of reported deaths from acute lung diseases (bronchitis, pneumonia, pleurisy and asthma) during the year was 3,937, and the weekly average was 76. The greatest number of deaths reported from this group of causes in a single week was 217, in the week ending March 2; and the least number was 16, in the week ending July 13. The average weekly number of reported deaths from these causes for each month was as follows :—

|                     |     |                      |    |
|---------------------|-----|----------------------|----|
| January, . . . . .  | 89  | July, . . . . .      | 27 |
| February, . . . . . | 146 | August, . . . . .    | 25 |
| March, . . . . .    | 162 | September, . . . . . | 28 |
| April, . . . . .    | 115 | October, . . . . .   | 48 |
| May, . . . . .      | 80  | November, . . . . .  | 68 |
| June, . . . . .     | 41  | December, . . . . .  | 80 |

The months having the greatest number of reported deaths from these causes were February and March, and those having the least number were July and September. The ratio of reported deaths

acute lung diseases to the reported mortality from all causes 135.9 per 1,000. The estimated death rate per 1,000 of the living population from these causes was 2.63, as compared with for the previous year.

#### TYPHOID FEVER.

The total number of reported deaths from this cause was 405, and the weekly average was 8. The greatest number reported in any week from this cause was 23, in the week ending September 1, and the least number was 2, in the weeks ending January 19, February 2, 16, 23 and June 29. The average weekly number of deaths reported from this cause for each month was as follows:—

|                     |   |                      |    |
|---------------------|---|----------------------|----|
| January, . . . . .  | 4 | July, . . . . .      | 5  |
| February, . . . . . | 2 | August, . . . . .    | 12 |
| March, . . . . .    | 5 | September, . . . . . | 16 |
| April, . . . . .    | 6 | October, . . . . .   | 12 |
| May, . . . . .      | 5 | November, . . . . .  | 10 |
| June, . . . . .     | 5 | December, . . . . .  | 11 |

The months having the greatest number of reported deaths from this cause were August, September and November, and those having the least were January, February and May. The ratio of reported deaths from typhoid fever to the reported mortality from all causes was 14.0 per 1,000, and the ratio to the reporting population was 27 per 1,000, as compared with .28 in the previous year.

#### DIPHTHERIA AND CROUP.

The total number of reported deaths from diphtheria and croup in 1905 was 1,289, and the average number in each week was 25. The greatest number reported in a single week from these combined causes was 50, in the week ending November 9; and the least number was 6, in the week ending July 6. The average weekly number of reported deaths from these causes for each month was as follows:—

|                     |    |                      |    |
|---------------------|----|----------------------|----|
| January, . . . . .  | 32 | July, . . . . .      | 12 |
| February, . . . . . | 29 | August, . . . . .    | 16 |
| March, . . . . .    | 18 | September, . . . . . | 25 |
| April, . . . . .    | 21 | October, . . . . .   | 28 |
| May, . . . . .      | 17 | November, . . . . .  | 41 |
| June, . . . . .     | 18 | December, . . . . .  | 42 |

The months having the greatest number of reported deaths per 1,000 from these causes were January, November and December,

and those having the least number were May, July and August. The ratio of deaths from diphtheria and croup to the reported mortality from all causes was 44.48 per 1,000, and the death rate of the reporting population was 86 per 1,000, that of the previous year being 95.

#### SCARLET FEVER.

The reported deaths from scarlet fever in 1895 were 312, and the average weekly number was 6. The greatest number of reported deaths from this cause in a single week was 13, in the weeks ending February 2 and April 13, and the least number reported in a single week was 1, in the weeks ending October 5 and November 9. The average weekly number reported in each month was as follows:—

|                     |    |                      |   |
|---------------------|----|----------------------|---|
| January, . . . . .  | 9  | July, . . . . .      | 6 |
| February, . . . . . | 10 | August, . . . . .    | 4 |
| March, . . . . .    | 8  | September, . . . . . | 5 |
| April, . . . . .    | 8  | October, . . . . .   | 3 |
| May, . . . . .      | 8  | November, . . . . .  | 2 |
| June, . . . . .     | 6  | December, . . . . .  | 3 |

The months having the greatest number of deaths from this cause were February and March, and those having the least number were October and November. The ratio of deaths from this cause to the reported deaths from all causes was 10.80 per 1,000, and the death rate of the reporting population from this cause was .21 per 1,000, that of the previous year being .32.

#### MEASLES.

The total number of reported deaths from measles in 1895 was 71. The greatest number in a single week was 8. There were twenty-two weeks in which no deaths from measles were reported. The average weekly number reported in each month was as follows:—

|                     |   |                      |   |
|---------------------|---|----------------------|---|
| January, . . . . .  | 2 | July, . . . . .      | 2 |
| February, . . . . . | 1 | August, . . . . .    | 0 |
| March, . . . . .    | 1 | September, . . . . . | 0 |
| April, . . . . .    | 2 | October, . . . . .   | 0 |
| May, . . . . .      | 2 | November, . . . . .  | 0 |
| June, . . . . .     | 4 | December, . . . . .  | 1 |

The ratio of deaths to the reporting mortality from all causes was 2.45 per 1,000, and the death rate from this cause was .047 per 1,000 of the reported population, as compared with .03 in 1894.

## DIARRHŒAL DISEASES.

the diseases in this group are diarrhœa, dysentery, cholera infantum and cholera infantum. From these causes combined the number of deaths reported in 1895 was 2,153, and the weekly average number was 41. The greatest number reported in a single week was 193, in the week ending August 8, and the least number 2, in the week ending January 19. The average weekly number of reported deaths from these causes in each month was as follows:—

|                     |    |                      |     |
|---------------------|----|----------------------|-----|
| January, . . . . .  | 4  | July, . . . . .      | 109 |
| February, . . . . . | 7  | August, . . . . .    | 158 |
| March, . . . . .    | 8  | September, . . . . . | 113 |
| April, . . . . .    | 5  | October, . . . . .   | 47  |
| May, . . . . .      | 8  | November, . . . . .  | 12  |
| June, . . . . .     | 13 | December, . . . . .  | 8   |

The months having the greatest number of reported deaths from these causes in 1895 were July, August and September, and those having the least were January, February and April. The deaths from these causes in the third quarter of the year constituted 77.7 per cent. of the number of deaths from the same causes for the year. The ratio of reported deaths to the reported mortality from all causes was 74.29 per 1,000, and the death rate of the reporting population from these causes was 1.44, as compared with 1894.

#### WHOOPING-COUGH, MALARIAL FEVER, ERYSIPELAS AND PUERPERAL FEVERS.

The essential statistics relating to these four diseases are embraced in the following table:—

|                            | Total Deaths Reported. | Weekly Averages. | Ratio per 1,000 of Reported Deaths from All Causes. | Ratio per 1,000 of Reporting Population. |
|----------------------------|------------------------|------------------|-----------------------------------------------------|------------------------------------------|
| Whooping-cough, . . . . .  | 128                    | 2.5              | 4.42                                                | .086                                     |
| Erysipelas, . . . . .      | 66                     | 1.3              | 2.30                                                | .044                                     |
| Malarial fever, . . . . .  | 35                     | .7               | .12                                                 | .023                                     |
| Puerperal fever, . . . . . | 11                     | .2               | .38                                                 | .007                                     |

## II.

FATALITY (*RATIO OF DEATHS TO CASES*) FROM CERTAIN INFECTIOUS DISEASES IN 1895.

The statistics presented in the following table are compiled from the published reports of local boards of health for the year 1895 which have been forwarded to the office of the State Board of Health. They are the figures representing the numbers of cases reported to local boards of health under the provisions of section 79 of chapter 80, Public Statutes.

The numbers of deaths are also obtained from the same reports, and the comparison of these two series of figures presents a fairly accurate method of arriving at the fatality from these diseases in the places from which they are reported. The figures representing the numbers of cases are probably less than the actual numbers, since some cases must necessarily escape registration through neglect to report or in consequence of faulty diagnosis.

*Cases of Infectious Diseases and Deaths reported to Local Boards of Health, 1895.*

| CITY OR TOWN.           | DIPHTHERIA<br>AND CROUP. |         | SCARLET<br>FEVER. |         | TYPHOID<br>FEVER. |         | MEASLES. |         |
|-------------------------|--------------------------|---------|-------------------|---------|-------------------|---------|----------|---------|
|                         | Cases.                   | Deaths. | Cases.            | Deaths. | Cases.            | Deaths. | Cases.   | Deaths. |
| Amesbury, . . . . .     | 24                       | 9       | 65                | 2       | 9                 | 1       | 225      | 4       |

Andover: small-pox, 1 case; not fatal.

The cities and towns embraced in the foregoing table are 84 in number, or 8 more than those presented in the previous year, and 1 more than those which reported for 1893. They comprise at least three-fourths of the population of the State.

The list contains the names of cities and towns containing about 15,000 more inhabitants than those which were reported last year, while one important city of about 50,000 population is omitted.

Bearing these changes in mind, the reported cases from diphtheria and croup were much in excess of those of any of the previous years embraced in the report, but the fatality (18.9) was much less. Comment upon these figures will be found elsewhere.

The reported cases of scarlet fever were considerably less than those reported in 1894, and the fatality (5.9 per cent.) was less.

The reported cases of typhoid fever were less than those of 1894, and the fatality (17.2) was but slightly greater.

The reported cases of measles were two and one-half times as many as those reported in 1894, and the fatality (1.5) was less.

The figures for 1895 are as follows:—

|                                                                                     |       |
|-------------------------------------------------------------------------------------|-------|
| Reported cases of diphtheria and croup, . . . . .                                   | 7,856 |
| Registered deaths from diphtheria and croup in the same cities and towns, . . . . . | 1,484 |
| Fatality (per cent.), . . . . .                                                     | 18.9  |
| Reported cases of scarlet fever, . . . . .                                          | 6,050 |
| Registered deaths from scarlet fever in the same cities and towns, . . . . .        | 357   |
| Fatality (per cent.), . . . . .                                                     | 5.9   |
| Reported cases of typhoid fever, . . . . .                                          | 2,665 |
| Registered deaths from typhoid fever in the same cities and towns, . . . . .        | 458   |
| Fatality (per cent.), . . . . .                                                     | 17.2  |
| Reported cases of measles, . . . . .                                                | 5,033 |
| Registered deaths from measles in the same cities and towns, . . . . .              | 75    |
| Fatality (per cent.), . . . . .                                                     | 1.5   |

The following table presents the summary of these statistics for five years 1891–1895:—

*Reported Cases of Infectious Diseases in Massachusetts.*

*Diphtheria and Croup.*

|                                 | 1891. | 1892. | 1893. | 1894. | 1895. | TOTAL. |
|---------------------------------|-------|-------|-------|-------|-------|--------|
| Reported cases, . . . . .       | 2,444 | 3,033 | 2,919 | 4,936 | 7,856 | 21,188 |
| Deaths, . . . . .               | 575   | 891   | 926   | 1,376 | 1,484 | 5,252  |
| Fatality (per cent.), . . . . . | 23.5  | 29.2  | 31.7  | 27.9  | 18.9  | 24.8   |

*Reported Cases of Infectious Diseases in Massachusetts — Concluded.**Scarlet Fever.*

|                                 | 1891. | 1892. | 1893. | 1894. | 1895. | TOTAL. |

*Typhoid Fever.*

|                                 | 1891. | 1892. | 1893. | 1894. | 1895. | TOTAL. |
|---------------------------------|-------|-------|-------|-------|-------|--------|
| Reported cases, . . . . .       | 2,414 | 1,892 | 2,457 | 2,814 | 2,065 | 12,342 |
| Deaths, . . . . .               | 460   | 435   | 492   | 483   | 456   | 2,333  |
| Fatality (per cent.), . . . . . | 19.0  | 23.0  | 20.0  | 17.0  | 17.2  | 19.1   |

*Measles.*

|                                 | 1891. | 1892. | 1893. | 1894. | 1895. | TOTAL. |
|---------------------------------|-------|-------|-------|-------|-------|--------|
| Reported cases, . . . . .       | 5,861 | 783   | 6,290 | 2,051 | 5,033 | 20,018 |
| Deaths, . . . . .               | 84    | 31    | 98    | 37    | 75    | 325    |
| Fatality (per cent.), . . . . . | 1.4   | 4.0   | 1.6   | 1.8   | 1.5   | 1.6    |

Considerable interest has been manifested recently in the mortality of cases reported as croup, but the impossibility of obtaining reliable statistics under the present system of reporting is apparent, since all reported cases of diphtheria and croup are embraced under one title in the published reports.

In England reported cases of croup have been placed in a separate list since 1892, as shown in the following table, which presents the fatality of diphtheria and croup separately. From this table it appears that the fatality from diphtheria for the three years 1892-94 was 23.3 per cent. of the reported cases, and that of croup was 40.7 per cent. The report also presents the following comment in support of the view that the fatality for croup is still greater than these figures would appear to show:—

The figures in the column of deaths from “membranous croup” do not include all the deaths which occurred from membranous croup, for, although that disease is considered to be related to diphtheria, the Registrar-

General's returns do not separate the deaths from those due to spasmodic croup, which is not a notifiable disease. It is believed, however, that in cases of membranous croup prove fatal they are often registered as diphtheria.

## ENGLAND.

| Mean fatality, per cent., | 23.8        |         | 40.7   |         | -      |         | 24.4      |

The following figures present the fatality from diphtheria, scarlet fever and typhoid fever in England, as reported by the Local Government Board of England for the years 1890-94:—

|                          | 1890. | 1891. | 1892. | 1893. | 1894. |
|--------------------------|-------|-------|-------|-------|-------|
| diphtheria, . . . . .    | 25.5  | 23.7  | 23.6  | 24.5  | 25.1  |
| scarlet fever, . . . . . | 8.0   | 5.8   | 4.4   | 4.2   | 4.8   |
| typhoid fever, . . . . . | 19.9  | 20.8  | 17.8  | 17.0  | 17.5  |

## III.

The following summary embraces the returns of diseases "dangerous to public health" made to the State Board of Health under the provisions of chapter 302 of the Acts of 1893. Since the act in question did not specify the diseases intended to be reported to the Board (except small-pox), the Board issued a circular, in which it expressed its opinion as to the particular diseases which should be reported under the provisions of this act. They were the following: *small-pox, scarlet fever, measles, typhoid fever, diphtheria, membranous croup, cholera, yellow fever, typhus fever, cerebro-spinal meningitis, hydrophobia, malignant pustule, leprosy and trichinosis.*

The report of 1893 embraced the returns of the fractional year only which immediately followed the enactment of the statute, while those of 1894 were for a full year.

The whole number of cases of infectious diseases reported in 1895 was 21,307, which were divided as follows:—

|                                                   |        |
|---------------------------------------------------|--------|
| Reported cases of small-pox, . . . . .            | 1      |
| Reported cases of diphtheria and croup, . . . . . | 7,806  |
| Reported cases of scarlet fever, . . . . .        | 6,194  |
| Reported cases of typhoid fever, . . . . .        | 2,438  |
| Reported cases of measles, . . . . .              | 4,868  |
| Total, . . . . .                                  | 21,307 |

The summary for the years 1893, 1894 and 1895 is as follows:—

|                   | REPORTED CASES OF |                       |                |                |          |
|-------------------|-------------------|-----------------------|----------------|----------------|----------|
|                   | Small-pox.        | Diphtheria and Croup. | Scarlet Fever. | Typhoid Fever. | Measles. |
| 1893, . . . . .   | 35                | 1,109                 | 2,914          | 1,525          | 1,503    |
| 1894, . . . . .   | 181               | 4,178                 | 6,731          | 2,372          | 2,133    |
| 1895, . . . . .   | 1                 | 7,806                 | 6,194          | 2,438          | 4,868    |
| Totals, . . . . . | 217               | 13,093                | 15,839         | 6,335          | 8,504    |

| January, . . . . .   | 20.4                     | 9.5  | 25.4              | 14.9 | 4.3               | 6.4  | 11.1     | 8.3  |
| February, . . . . .  | 20.0                     | 9.3  | 23.2              | 13.6 | 2.1               | 3.1  | 10.9     | 8.1  |
| March, . . . . .     | 16.7                     | 7.8  | 24.3              | 14.3 | 2.1               | 3.1  | 22.1     | 16.5 |
| April, . . . . .     | 11.4                     | 5.3  | 15.4              | 9.0  | 2.2               | 3.3  | 29.2     | 21.8 |
| May, . . . . .       | 12.5                     | 5.8  | 14.4              | 8.5  | 3.2               | 4.8  | 28.3     | 21.1 |
| June, . . . . .      | 20.5                     | 9.6  | 16.9              | 9.9  | 3.4               | 5.1  | 32.0     | 23.9 |
| July, . . . . .      | 14.1                     | 6.6  | 11.6              | 6.8  | 3.8               | 5.7  | 4.8      | 3.6  |
| August, . . . . .    | 16.0                     | 7.5  | 11.2              | 6.6  | 12.4              | 18.5 | 3.4      | 2.6  |
| September, . . . . . | 18.9                     | 8.8  | 13.3              | 7.8  | 13.8              | 20.6 | 1.5      | 1.1  |
| October, . . . . .   | 24.4                     | 11.4 | 16.0              | 9.4  | 15.0              | 22.4 | 1.8      | 1.3  |
| November, . . . . .  | 46.0                     | 21.5 | 19.1              | 11.2 | 11.3              | 16.9 | 6.1      | 4.6  |
| December, . . . . .  | 36.1                     | 16.9 | 13.3              | 7.8  | 6.2               | 9.2  | 9.1      | 6.8  |
| Mean, . . . . .      | 21.4                     | 10.0 | 17.0              | 10.0 | 6.7               | 10.0 | 13.4     | 10.0 |

The figures in the foregoing table are introduced for the purpose, of comparing the prevalence of one disease with another, but the purpose of presenting the reports of each month upon a uni-

form basis of comparison, month by month, so that the relative intensity of each disease is shown for each month. The method also has the advantage of eliminating the apparent errors of computation arising from the unequal length of the months.

The figures may be read as follows: for example, the mean daily number of reported cases of diphtheria and croup in January was 20.4; of scarlet fever, 25.4; of typhoid fever, 4.3; and of measles, 11.1 (see columns marked A); and the mean daily number of the same diseases for the whole year 1895 was, respectively, 21.4—, 17.0—, 6.7 and 13.4. Assuming a standard of 10 as the daily mean of each disease for the year, the ratios for January were as follows: diphtheria and croup, 9.5; scarlet fever, 14.9; typhoid fever, 6.4; and measles, 8.3. (See columns marked B.) That is to say, for each 10 reported cases of diphtheria and croup occurring throughout the year, as a daily mean, there were 9.5 daily in January, 9.3 in February, etc.

The following table presents the numbers of cases of each disease reported from each city and town in 1895. The whole number of reporting cities and towns is less than that of the previous year; but, while the number of small towns reporting is less, the number of towns having over 5,000 population is greater.

Where the name of a city or town occurs both in Section II. and in Section III. of this summary, the difference in numbers may be taken as the deficiency in returns made by the local board to the State Board of Health.

*Cases of Infectious Diseases reported to the State Board of Health from One Hundred and Fifty-five Cities and Towns during 1895*

One case of small-pox in Andover.

The following list comprises the cities and towns which failed to report (under the provisions of the statute) to the State Board of

Health. It is but just to state that in many of the towns named in group IV. and in some of those in group III. it is quite probable that no cases of infectious disease occurred.

The Board will forward to the local board of health of any place the postal cards necessary for reporting on application from such local board of health.

## IV.

The following summary comprises the results obtained from the tabulation of the returns required by chapter 218 of the Acts of 1894, whereby the board of health of each city and populous town is directed to send to the State Board of Health an annual statement of the deaths in such city or town upon a blank form furnished by the State Board.

The whole number of cities and towns included in this list is eighty-five, of which number eighty complied with the statute. The total population of these cities and towns by the census of 1895 was 1,971,817. The number of deaths registered in these cities and towns was 37,828, and the death rate was 19.18 per 1,000.

*Sexes.* — The number of deaths of males was 19,109, or 50.5 per cent. of the whole number of deaths; and the deaths of females were 8,702, or 49.5 per cent.

*Ages.* — The deaths of infants under one were 8,634, or 22.8 per cent. of the total mortality; those of children under five years of age were 12,425, or 32.8 per cent. of the whole.

In conformity with the age distribution recommended by Körösi, the deaths of those whose ages were known were as follows: —

| AGES.                   | Percentages. | AGES.                  | Percentages. |
|-------------------------|--------------|------------------------|--------------|
| Under 1 year, . . . . . | 22.9         | 20-50, . . . . .       | 25.7         |
| 1-20, . . . . .         | 17.9         | All over 50, . . . . . | 33.5         |

*Months and Quarters.* — The number of deaths in each quarter of the year is shown in the following table: —

|                           | Deaths. | Percentages. |                           | Deaths. | Percentages. |
|---------------------------|---------|--------------|---------------------------|---------|--------------|
| First quarter, . . . . .  | 10,181  | 26.9         | Fourth quarter, . . . . . | 8,712   | 23.0         |
| Second quarter, . . . . . | 8,566   | 22.7         | Date unknown, . . . . .   | 10      | —            |
| Third quarter, . . . . .  | 10,359  | 27.4         | Total, . . . . .          | 37,828  | 100.0        |

The intensity of the seasonal death rate is shown in the following table, the method employed being explained on page 730, in Section III., relating to disease notification.

*Seasonal Intensity of the Death Rate.*

|                   | Mean Daily Deaths per Month. | Mean Rate compared with a Standard of 100. |                    | Mean Daily Deaths per Month. | Mean Rate compared with a Standard of 100. |
|-------------------|------------------------------|--------------------------------------------|--------------------|------------------------------|--------------------------------------------|
| January, . . . .  | 99.7                         | 96.2                                       | August, . . . .    | 126.4                        | 122.0                                      |

| May, . . . .      | 93.1                         | 89.9                                       | December, . . . .  | 94.4                         | 91.1                                       |
| June, . . . .     | 88.8                         | 80.9                                       | Annual mean, . .   | 103.6                        | 100.0                                      |
| July, . . . .     | 101.7                        | 98.2                                       |                    |                              |                                            |

*Causes of Death.*—The list of causes of death embraced in this summary includes those from the principal infectious diseases, including consumption, together with certain other groups of destructive diseases and those from violence.

The ratio of deaths to the living population is also presented, since this method of presentation, especially in a census year, constitutes a better method of indicating the incidence of each cause of death upon the living population than the ratio of the deaths from each disease or cause of death to the total mortality.

## HEALTH OF TOWNS.

---

The following digest contains such extracts from the annual reports of the local boards of health of cities and towns as pertain to matters of sanitary importance in the different municipalities from whose reports they are quoted.

The most notable point observed in these reports is the unanimity with which local boards have entered upon the work of controlling the spread and limiting the mortality from diphtheria by the introduction of the use of antitoxin. In nearly all the cities and large towns and in many of the smaller towns the use of this agent has become quite general, and the success attained by such use appears to have been uniformly good. It is to be hoped that, along with the gain derived from this additional aid to the sanitary authority, the usual and quite important measures of isolation, notification, disinfection and general municipal cleanliness will not be slackened in the least degree.

Attention is especially called to the statement in the extract from the report of the Concord board of health relative to the authority or jurisdiction of a local board of health over a public institution existing within the limits of the area over which the local board of health acts. There are at present many such institutions and establishments located in the different cities and towns, and their number is annually increasing. A full statement of the question involved has been published by the authorities of the State Reformatory at Concord.

### HEALTH OF TOWNS.

#### AMESBURY.

The election of the board of health was illegal. The duties of the board were devolved to the selectmen, and they availed themselves of a statutory provision and appointed an agent.

The vault and cesspool method of caring for the sewage has been in general use so long that some sections of the town are saturated with filth, that in some instances vault fluids have leaked through into adjacent houses.

A few cases of tuberculosis have been discovered in our town, and the animals quarantined and slaughtered by order of the State officers. Every dairyman should have his herd tested, for it will be only a few years when consumers of milk will demand a certified article.

Diphtheria has been unusually severe, there having been 24 cases, 9 of which were fatal. Up to October 18 there have been 8 cases, with 4 deaths; since the above date there have been 16 cases, with 3 deaths. In 12 of these 16 cases antitoxin was used, with only 2 deaths; in 4 of these 16 cases antitoxin was not used, and one died. In one of the fatal cases where antitoxin was used the case had advanced two weeks before the use of the drug, and the other case was advanced from Tuesday to Friday. It is necessary to use antitoxin early in the development of the disease, to get the best results. A supply of antitoxin is constantly kept on hand by this board, and in cases of poor families is furnished free of charge.

#### ANDOVER.

During the year twenty-six cases of nuisance have been investigated by the board. Advice in regard to the location of six cesspools has been given. Two examinations and certificates for plumbers have been received, and one permit granted to keep a boarding-house for infants.

The various slaughter houses and rendering establishments have been under the supervision of your Board, and have been visited frequently.

#### ARLINGTON.

Our town the past year has been remarkably free from the prevalence of epidemics of contagious or other diseases.

The board has given prompt attention to all calls for its services to abate nuisances and remedy sanitary defects.

In most cases parties interested have readily responded to requirements of the board, with results satisfactory to all concerned.

#### ATTLEBOROUGH.

The present board early in the year published a notice inviting all citizens who knew of any nuisance or any condition which they deemed a nuisance or a menace to the public health to notify the board in writing. Owing, doubtless, to this fact, it is safe to say that there have been more cases of this nature reported during the past year than in any preceding year in the history of the town. The board has made a special effort to remedy an evil which we believe has, in the past, been the cause of much infectious illness in our town.

Of the animals killed during the past year in town for beef purposes, twelve have been found to be afflicted with tuberculosis. Some of these animals, apparently healthy, have been used as milk producers. We wish it were possible to require every milk producer to have his herd examined before he is allowed to dispose of a single quart of milk.

#### AYER.

Four cases of typhoid fever were contracted out of town, three occurred in families using water from old wells, five were of unknown origin.

#### BELMONT.

The town has been remarkably free from contagious diseases during the last year. Only one death occurred during the year from contagious disease, that being from diphtheria.

The completion of the main line of the metropolitan sewer in the summer 1895 was a matter looked upon by the board of health as one of great importance toward promoting the good sanitary condition of the town. This completion necessitated the adoption of plumbing regulations, which were accordingly drawn up by the board, accepted by the town and incorporated as a part of its by-laws.

#### BILLERICA.

We have from time to time inspected wells, cesspools and vaults and made analyses of drinking water, both in the Centre and North villages, and have advised such cleansing and changes of construction as seemed to be demanded in the interest of health. We cannot too earnestly call attention to the importance of keeping the drinking water free from all pollution, by drainage, from cesspools or vaults.

#### BLACKSTONE.

During the year the board attended to all complaints made to them, and most cases with good results; but in a few cases the persons to whom instructions to abate nuisances were given did not promptly attend to them, either from neglect or for the purpose of making themselves thoroughly disagreeable. All cases have been properly examined, however, and such suggestions made as are likely to obviate future cause of complaint.

## BOSTON.

The total number of deaths for the year was 11,329, a decrease from the previous year of 191 deaths. The population, as estimated at the end of the year, is 501,083. The death rate for the year, as calculated on this population, is 22.60 per 1,000 inhabitants. This rate is less by .38 than that of the previous year, and the lowest since 1889.

There were 229 less deaths from diphtheria than in 1894, although the number of cases of diphtheria reported was largely increased on account of the larger number discovered among the pupils in the public schools by the medical inspectors of schools, and the bacteriological tests in the otherwise unrecognized cases. The ratio of deaths to the number of cases of diphtheria reported has been reduced by more than one-half.

Very complete tables are published, showing the mortality from infectious diseases in Boston in 1895, by months, sex, nativity, color and ages.

*Bacteriology.*

The bacteriological work in culture diagnosis of diphtheria, begun by the board of health in October, 1894, has been continued at the Harvard Medical School Laboratory under the charge of Prof. Harold C. Ernst.

*Medical Inspection of Schools and Supervision of Contagious Diseases.*

The inspection of schools, which was commenced in November, 1894, and described fully in our last annual report, has been followed through the year with excellent results. The schools have been visited daily, and all children who have complained of illness or appeared to the teachers to be ill have been examined by the visiting physician, who, in all cases, advises the teachers what to do with the pupil. This work has now been in progress for fourteen months, and it has demonstrated the fact that there are not only many cases of contagious diseases to be found in the schools, and which require early recognition and removal, but that there are large numbers of school children whose illness and whose disposition by the teacher require the decision of a competent physician.

For the fourteen months ending Dec. 31, 1895, 16,790 pupils were examined, 10,737 of whom were found to be ill; 6,053 were found not to be ill, and 2,041 of these were too ill to remain in school for the day.

Seventy-seven cases of diphtheria, 28 cases of scarlet fever, 116 of measles, 28 of chicken-pox, 69 of pediculosis, 47 of scabies, 47 of mumps, 33 of whooping-cough and 8 of congenital syphilis were found in children sitting in their seats spreading these diseases to other children. The remaining 10,372 sick children were suffering from a large variety of other diseases.

Commendable efforts were made by the board in the direction of a general improvement of the sanitary condition of the school-houses of Boston. In view of the fact that contagious diseases may easily be spread in the schools through the medium of infected books, pencils, sponges, slates, desks and other surfaces of the school-room, handled or used by the children, the following recommendation was made to the school committee in 1894 :—

*To the Honorable School Committee, City of Boston.*

GENTLEMEN :—The board of health begs respectfully to recommend that the desks, chairs, window-sills, wainscotings, doors, door-knobs and such other surfaces as are likely to be handled by the children within the school buildings be carefully rubbed with cloths or sponges, wet with a solution of corrosive sublimate (one part of corrosive sublimate to one thousand parts of water), as often as every Saturday during the school year; that the floors of the school-houses be well covered with sawdust thoroughly wet with the same disinfecting solution, at least once a week, and the sawdust swept up and burned; that the use of all slates, slate-pencils and sponges for slate use be discontinued, and that paper and lead-pencils be substituted.

The disinfection of books is scarcely practicable except by fire, and the board would recommend, whenever it is known that a book has been handled by a pupil who was, at the time, affected with a contagious disease, or the book is otherwise much soiled, it be immediately burned.

Very respectfully,

THE BOARD OF HEALTH,

By S. H. DURGIN, *Chairman.*

The following action was subsequently taken by the school committee :—

*Report of Committee on Hygiene and Physical Training.*

The committee on hygiene and physical training, to whom was referred—October 27—an order “that the committee on hygiene and physical training consider and report what action, if any, can be taken by this board to disinfect, or render aseptic, the school-books used in the schools,” report that careful consideration was given to the order, but no practical method could be found.

Up to this time nothing but fire is considered a sure disinfectant, therefore the books could be rendered aseptic only by destruction at stated intervals. As this committee do not feel at liberty to recommend this action, they have no suggestion to offer concerning the disinfection of books; however, that it will be entirely practicable to discontinue the use of slates and slate-pencils, and the necessary accompaniment, sponges. There are three good reasons why the use of slates and slate-pencils should be discontinued :—

*First*, a light gray mark upon a slightly darker gray surface is more or less distinct, and trying to the eyesight.

*Second*, the resistance of the hard pencil upon the hard slate is tiring to the muscles, and the resistance, to which the muscles are trained by the use of slates and slate-pencils, must be overcome when beginning to write with pencil or pen on paper.

*Third*, and last, but not least, the use of slates, slate-pencils and sponges is a very uncleanly custom, and leads to and establishes very uncleanly habits.

The committee also deprecate the custom of the daily distribution and regathering of lead-pencils, for the reasons which must be apparent to all after a moment's consideration. The pencil not infrequently finds a resting-place between the teeth and lips, and it is hardly to be supposed that the same pencil will be given to the same pupil the next day.

The committee, therefore, recommend the passage of the following orders:—

*Ordered*, That the use of slates and slate-pencils and sponges be discontinued, and that paper, lead-pencils and rubber erasers be supplied in their places.

*Ordered*, That lead-pencils and erasers be given to each pupil at the beginning of the term, to be retained by the pupil for his sole use during the school year.

JUNE 25, 1896.

*Ordered*, That the committee on accounts be requested to direct janitors to cover during the summer vacation all the floors of school-houses with sawdust wet with a solution of bichloride of mercury (one part of bichloride of mercury to three thousand parts of water), and sweep the sawdust before it becomes dry; also sponge off all chairs, desks, window-sills, wainscotings, doors and door-knobs with a solution of the same strength, and wipe off with a wet cloth before they become dry. All applications may be made with a sponge or cloth mounted upon a handle or stick, so that the hands need not be put into the solution.

### *Diphtheria.*

A detailed account of the work of culture diagnosis of diphtheria and the production of antitoxin is presented.

The total examinations made for the whole period have been 8,644; the lowest daily average for any month was 11, during August and September, and the highest 33, during December, 1895. The daily average of November, 1894, was 13; the daily average of November, 1895, was 28; of December, 1894, 27; of December, 1895, 33, — showing a marked increase in the use of this method of diagnosis by the profession.

The total number examined in November, 1894, was 397; in November, 1895, 835; in December, 1894, 823; in December, 1895, 1,023.

There were sent in 402 cases showing no growth, and these are to be neglected, leaving 8,242 cases in which the results were more or less satisfactory. Of these, 1,717 were found to contain the bacilli of diphtheria, a percentage of a little less than 21.

### *The Production of the Antitoxin of Diphtheria.*

The preparation of this material was begun in December, 1894, and has been vigorously and successfully prosecuted since that time. Some time was consumed in getting together the necessary apparatus, animals and assistants. The cultures have all been made and the injections of the horses have been carried out at the place originally selected on Gallop's Island.

The following table has been prepared, which includes the totals from all the horses in the time that they have all been immunized, i.e., from the last August, 1895:—

|                        | Cubic Centimeters<br>of Serum. |
|------------------------|--------------------------------|
| Horse IV., . . . . .   | 2,500                          |
| Horse V., . . . . .    | 3,500                          |
| Horse VIII., . . . . . | 1,700                          |
| Horse IX., . . . . .   | 2,000                          |
| Horse X., . . . . .    | 3,500                          |
| Horse XI., . . . . .   | 2,500                          |
| Total, . . . . .       | 15,700                         |

or nearly 1,000 cubic centimeters a week.

There have been returned at this date (Jan. 15, 1896) reports of the results of the use of the antitoxin supplied by the board in 743 cases, divided as follows:—

|                       |     |
|-----------------------|-----|
| Recoveries, . . . . . | 550 |
| Deaths, . . . . .     | 97  |
| Total, . . . . .      | 647 |

giving a mortality of a shade under 15 per cent., which is remarkable when compared with the general mortality of this disease, never under 27 per cent. in Boston and 27.06 per cent. in 1894.

To the foregoing are to be added 96 cases in which the serum was used for immunizing, making a total of 743 cases in all.

It has seemed to be interesting to work out the percentage of mortality in private practice, so far as it is shown by our returns. Of cases in which the antitoxin of your board has been used out of the hospitals, there have been reported:—

|                       |    |
|-----------------------|----|
| Recoveries, . . . . . | 72 |
| Deaths, . . . . .     | 7  |
| Total, . . . . .      | 79 |

which gives a mortality of 8 per cent.

#### *Garbage Disposal.*

If this material should be disposed of in the kitchen there would no longer be any danger of a public plant for the cremation or reduction of garbage in any residential district of the city; there would be no more ill-carts in the streets; there would be fifty thousand less swill-barrels in the back yards, and a saving of two hundred thousand dollars annually to our city treasury.

*House-to-house Inspection.**Recapitulation.*

|                                          |   |   |   |   |   |   |   |   |        |
|------------------------------------------|---|---|---|---|---|---|---|---|--------|
| Whole number examined,                   | . | . | . | . | . | . | . | . | 366    |
| Bad odors found,                         | . | . | . | . | . | . | . | . | 116    |
| Defective drains found,                  | . | . | . | . | . | . | . | . | 122    |
| Lack of traps found,                     | . | . | . | . | . | . | . | . | 77     |
| Offensive vaults found,                  | . | . | . | . | . | . | . | . | 1      |
| Damp or unclean yards,                   | . | . | . | . | . | . | . | . | 11     |
| Damp or unclean cellars,                 | . | . | . | . | . | . | . | . | 19     |
| Using furnaces,                          | . | . | . | . | . | . | . | . | 107    |
| Furnaces without proper air supply,      | . | . | . | . | . | . | . | . | 14     |
| Using steam heat or hot water,           | . | . | . | . | . | . | . | . | 8      |
| Water-closets found,                     | . | . | . | . | . | . | . | . | 364    |
| Old style or faulty water-closets found, | . | . | . | . | . | . | . | . | 64     |
| Offensive water-closets found,           | . | . | . | . | . | . | . | . | 34     |
| Ventilation to soil-pipe or drain found, | . | . | . | . | . | . | . | . | 178    |
| Offensive cesspools found,               | . | . | . | . | . | . | . | . | 14     |
| Percentage of defective drains,          | . | . | . | . | . | . | . | . | 33.33  |
| Percentage of defective trapping,        | . | . | . | . | . | . | . | . | 21.04  |
| Percentage of unventilated drains,       | . | . | . | . | . | . | . | . | 51.37  |
| Total number of nuisances abated,        | . | . | . | . | . | . | . | . | 11,679 |

*Disinfection after Infectious Diseases.*

|                               |   |   |   |   |   |   |   |   |        |
|-------------------------------|---|---|---|---|---|---|---|---|--------|
| Diphtheria,                   | . | . | . | . | . | . | . | . | 3,450  |
| Scarlet fever,                | . | . | . | . | . | . | . | . | 1,486  |
| Phthisis,                     | . | . | . | . | . | . | . | . | 6      |
| Measles,                      | . | . | . | . | . | . | . | . | 11     |
| Total,                        | . | . | . | . | . | . | . | . | 5,095  |
| Rooms disinfected,            | . | . | . | . | . | . | . | . | 10,155 |
| Grand total of disinfections, | . | . | . | . | . | . | . | . | 56,888 |

*Materials Used.*

|                                 |   |   |   |   |   |   |   |        |
|---------------------------------|---|---|---|---|---|---|---|--------|
| Bichloride of mercury (pounds), | . | . | . | . | . | . | . | 1,575  |
| Chloride of lime (pounds),      | . | . | . | . | . | . | . | 36,875 |
| Sulphur (pounds),               | . | . | . | . | . | . | . | 44,899 |
| Copperas (pounds),              | . | . | . | . | . | . | . | 3,150  |
| Muriatic acid (carboys),        | . | . | . | . | . | . | . | 12     |
| Houses ordered vacated,         | . | . | . | . | . | . | . | 112    |

*Public Baths, Number of Bathers in June, July, August and September.*

|                        | 1894.     | 1895.   |
|------------------------|-----------|---------|
| Total men and boys,    | 860,944   | 589,779 |
| Total women and girls, | 221,731   | 177,046 |
| Total of both sexes,   | 1,082,675 | 766,825 |

The subject of maintaining bath-houses all the year round was the subject of a special recommendation by His Honor the mayor in his inaugural address to the city council, and a special commission has since been appointed by him to consider the subject, and make such recommendations with a view to establishing such accommodations as may be deemed expedient. The supplying of public bathing facilities during the winter as well as during the summer months has the cordial approval of the board of health, as being in the line of promoting the public health.

#### *Examination of Plumbers.*

The examining board held 44 meetings and examined 258 candidates for plumbers' licenses; 93 were for master plumbers' licenses, and 50, or 52 per cent., passed the examination and were licensed; 165 were examined for journeymen plumbers' licenses, and 106, or 64 per cent., passed the oral examination and were notified to report at the shop for a practical test. Of the 106 candidates who passed the oral examinations, 77 passed successful examinations in the shop and were given licenses.

#### *Lying-in Hospitals.*

During the year 423 confinements have taken place in the licensed hospitals, and no deaths have been reported.

#### *Stables.*

There were 248 applications, and 198 were granted.

#### *Prosecutions.*

During the year there have been 30 prosecutions for violations of various health laws. In these cases there were 25 convictions, 2 acquittals, 2 were *vol-prossed* and 1 is still pending.

Of the convictions, perhaps the most important was that of a physician for failing to report a case of contagious disease which he had been called to attend. In this case a fine of fifty dollars was imposed in the lower court, and, after an appeal and trial before a jury, the judgment of the lower court was affirmed, and the fine increased to one hundred dollars.

The physicians of the board examined 39 cases reported as small-pox, one of which proved to be such.

The bodies of 454 persons dying without a physician were also examined, determine the causes of death.

#### *Animals killed at Abattoir.*

|                   |        |
|-------------------|--------|
| Cattle, . . . . . | 25,814 |
| Calves, . . . . . | 14,141 |
| Sheep, . . . . .  | 77,906 |
| Swine, . . . . .  | 470    |

*Animals condemned.*

|                             | Number. | Weight. |
|-----------------------------|---------|---------|
|                             |         | Pounds. |
| Cows, . . . . .             | 52      | 22,864  |
| Steers, . . . . .           | 2       | 1,540   |
| Bulls, . . . . .            | 1       | 630     |
| Calves, . . . . .           | 9       | 372     |
| Sheep, . . . . .            | 1       | 30      |
| Parts of animals, . . . . . | —       | 4,000   |
| Total, . . . . .            | 65      | 29,436  |

*Diseases found among Animals after having been killed and dressed at the Abattoir.*

| DISEASES.                  | Cattle. | Calves. | Sheep. |
|----------------------------|---------|---------|--------|
| Tuberculosis, . . . . .    | 49      | —       | —      |
| Actinomycosis, . . . . .   | 7       | —       | —      |
| Septicæmia, . . . . .      | 2       | —       | 1      |
| Puerperal fever, . . . . . | 2       | —       | —      |
| Bruised, . . . . .         | 1       | —       | —      |
| Immatured, . . . . .       | —       | 9       | —      |

*Tuberculosis.*

The following table shows the percentage of tuberculosis in cattle killed at abattoir with the intention of being used for food :—

| CLASS OF ANIMALS.                     | Number received. | Tuberculosis. | Percentage. |
|---------------------------------------|------------------|---------------|-------------|
| Whole number of all kinds, . . . . .  | 25,814           | 49            | 0.189       |
| Cows from eastern States, . . . . .   | 1,949            | 47            | 2.41        |
| Bulls from eastern States, . . . . .  | 157              | 1             | 0.63        |
| Steers from eastern States, . . . . . | —                | —             | —           |
| Cows from Buffalo, . . . . .          | 536              | 1             | 0.18        |
| Cows from western States, . . . . .   | 1,421            | —             | —           |
| Steers from western States, . . . . . | —                | —             | —           |

Under the head of "cows from eastern States" is understood those animals from all of the New England States, including Massachusetts.

*Inspection of Cattle.*

In accordance with the regulations of the board of health and an act of the Legislature, the work of inspection of cows kept for the production of milk has been continued during the past year. With one or two exceptions all cattle which upon inspection have shown any symptoms of tuberculosis have been subjected to the tuberculin test, and all animals which have shown a reaction to such test have been quarantined, and the State Board of Cattle Commissioners notified.

## BROCKTON.

The board is of the opinion that final disinfection after contagious diseases, which is required under the Public Statutes to be done to the satisfaction of the board, should be done by the board itself. It is the intention of the board the coming year to ask for an appropriation to carry out this work, and to employ some person to disinfect all premises and articles which, in its opinion, have been infected.

The following is a list of some of the principal complaints and nuisances investigated during the past year:—

|                                |     |
|--------------------------------|-----|
| Defective cesspools, . . . . . | 127 |
| Defective vaults, . . . . .    | 115 |
| Filthy yards, . . . . .        | 143 |
| Filthy cellars, . . . . .      | 24  |
| Bad drainage, . . . . .        | 33  |
| Animals buried, . . . . .      | 43  |

## BROOKLINE.

Nine cases of typhoid fever, several of which, if not all, were found on investigation to have been contracted away from home, is an exceedingly small number for a population of over sixteen thousand, and is the best possible evidence of the care taken to maintain the purity of our public water supply.

The board of health hospitals have been kept in readiness throughout the year, and have been used for the efficient isolation and care of 2 cases of scarlet fever and 21 cases of diphtheria. The only death occurring in the hospital was the case of a feeble little child, ill with both measles and diphtheritic croup, the latter disease being well advanced and beyond control when admitted to the hospital.

It is gratifying to be able to state that during the diphtheria epidemic in Brookline and the surrounding cities and towns in October, November and December, of the 18 patients admitted to the hospital, all going with their parents' approval or consent, and all of whom received one or more injections of antitoxin (in most cases furnished by the State Board), all re-

covered. The number of diphtheria patients reported in the town during the same time, many of whom also had antitoxin, was 42, of which number 9 died, or 21.4 per cent. During the epidemic and since, antitoxin has been furnished free by the board, on application, to physicians having patients who could ill afford to pay for it. The State Board antitoxin was supplied when available, otherwise Behring's, and excellent results were reported from both.

The value of the bacteriological test as a means of certain diagnosis, which is required to be made in all diphtheritic cases before they are released from quarantine, has been emphasized by the recent experiences here.

The need of improved public bathing facilities and of a new public swimming-bath, recommended in previous reports of this board as an important sanitary measure, has been recognized by the town, and the necessary steps for securing a new public bath-house, first-class in every respect, have been taken.

In the same pamphlet with the report of the board of health are published the reports of the inspectors of milk and of animals, also those of the sanitary inspector and of the town clerk on vital statistics. The report of the milk inspector presents the results of analysis of each one of more than two hundred samples, together with the names of the dealers.

#### CAMBRIDGE.

|                                             |       |
|---------------------------------------------|-------|
| Number of inspections made, . . . . .       | 2,313 |
| Number of subsequent inspections, . . . . . | 4,569 |
| Total, . . . . .                            | 6,882 |

#### *Hospital.*

In the year 1894 the prevalence of scarlet fever in Cambridge was greater than in any year since notification of diseases dangerous to the public health was made obligatory, and in the present year the same has been true of diphtheria.

Had there been during these years a suitable hospital for the reception of cases of these diseases at the disposal of the board, many cases might have been prevented and lives been saved. In the absence of such a hospital it has been the duty of this board (P. S., chap. 80, sect. 40), in view of the great prevalence of diphtheria in the city, to utilize as far as possible the small ward in the Cambridge Hospital for the reception of cases of this disease. They have also been compelled to use for a short time the Cottage Hospital on the almshouse grounds. While the accommodations afforded by these hospitals have not been adequate to the needs of the city, they have yet been of very great value in enabling us to check the spread of this disease. In these two hospitals combined 62 cases of

diphtheria have been cared for this year at the public expense; of this number, 9 died. The Cambridge Hospital also treated 9 private cases, among which there were no deaths. The fatality among the hospital cases was, therefore, 9 out of 71, or 12.7 per cent. Of these fatal cases it should be said that 3 were practically past hope when they reached the hospital, and expired shortly after reaching it.

#### *Disinfection.*

We are endeavoring to so train certain of our employees that the work of house disinfection may be intelligently and effectively done by them and under their direction, they being authorized to require the co-operation of the householders for such matters as can and should be done by the latter.

#### *Bacterial Examination.*

We are most clearly of opinion that the protection of the public health demands that this work, begun by this board during the past year, should be unremittingly carried on.

#### *Schools.*

What has thus far been accomplished is to prevent the return to the public schools of children who have had contagious disease, while they are yet capable of transmitting it, and to prevent the attendance at such schools of children from families wherein cases of such disease exist. This has been of the utmost importance; but there yet remain the following measures to be adopted before it can be said that the city has reasonably done its duty in the premises:—

1. The extension of the present system to the private and parochial schools of the city.
2. Establishing a system of school inspection by physicians appointed by this board, with a view of detecting cases of actual disease among the children present in school, and their prompt elimination.
3. Much greater attention than has heretofore been paid to the matter of cleansing of the school-rooms and school-houses.

We have already succeeded in partially extending this system to the parochial schools; i.e., notification of contagious diseases affecting the attendance of their scholars is now sent to those in charge of such schools.

#### CANTON.

Owing to an informality in the election of the board of health, the duties of the office devolved upon the selectmen.

Twenty-three complaints of nuisances have been filed, and each was at once abated.

## CHICOPEE.

Epidemic influenza, or "grippe," which appears to have become an annual visitor, was the principal acute disease affecting our people during the winter and spring, but, aside from its fewer victims and somewhat lessened severity, presented no new symptoms worthy of note.

Eight cases of typhoid fever is a good record, compared to the years previous to 1893, when our city stood among the first in the Commonwealth as a habitat of this disease. Here certainly is a testimonial to the greater cleanliness of the city, as well as to our better water supply. Some difficulty has been experienced in getting physicians to report cases of typhoid to the health department, though this is distinctly required by the regulations. Accordingly the board had mailed to every physician in the city a postal card *stating that typhoid fever must be reported*, that this was necessary not only for statistical purposes but also to enable the health authorities to investigate the sanitary conditions of the places where it occurred, and that co-operation in this matter would be insisted upon. Since then, so far as the board is aware, all cases have been promptly reported.

As our population increases, the need of some systematic and reliable method of garbage collection becomes more pressing.

## CLINTON.

The board has made arrangements with the State Board of Health for the keeping of a supply of antitoxin on hand for the use of physicians in this and adjoining towns. By this means several cases in Clinton and Bolton have been supplied earlier than could have been the case under the former method, and it is believed with marked benefit.

## COHASSET.

Complaints having been made of the impure condition of James Brook during the summer, the board of health carefully investigated the matter and did what they could to abate the nuisance. Believing the cause to have been the flowing of sewage into the brook, they requested all persons who convey the overflow of their cesspools thereto to cease doing so before April 1 next. A cheerful compliance with the above request will prevent the repetition of the nuisance the coming summer. The board have, as a precautionary measure, caused the brook to be cleaned and dug out from the bridge on Pleasant Street to its entrance to the harbor.

## CONCORD.

The plumbing in thirty-six houses has been inspected and passed during the year. This work is all new, being either in new houses, or new work in old houses. We can truthfully say that that part of the labor of this

board is worth all it costs. In our opinion this is most important, and it will be found to be especially so if a system of sewage disposal is established in the near future. By the agent's report it will be seen that he has inspected more places than ever before, and in the most thorough manner.

The agent was refused permission to inspect the premises in one case. The deputy superintendent of the Massachusetts Reformatory, acting under instructions from the superintendent, took the ground that none of the houses occupied by the officers and owned by the Commonwealth were subject to any inspection by the local board of health. After considerable correspondence with the superintendent and the prison commissioners, an opinion was finally obtained from the Attorney-General of the State. The opinion is expressed that, as the superintendent had sole control of the reformatory, and as the houses of the officers were a part of the institution, the local board of health could not inspect them without interfering with the discipline of the prison. It being admitted on our side that we had no rights inside the prison walls, the Attorney-General thought that it would be impossible clearly to draw the line, and hence that neither we nor the State Board had any right to inspect the property. We have rested our case there. Our only alternative is to go to the Legislature and try to get a bill passed, allowing local boards of health to inspect State property used as dwellings, wherever it may be found within their jurisdiction.

It seems to us decidedly inconsistent that, as a local board, we should not have the same rights to inspect the houses of the Commonwealth as we have to inspect those of a private individual; for, if an epidemic should break out, or even if an isolated case of contagious disease should appear in one of the houses owned by the Commonwealth, the local board of health would certainly be called upon to fumigate the building and take other measures to abate the trouble, and, if so, why should we not have the power to inspect the houses at first, and see that they are kept in a healthy condition?

#### COTTAGE CITY.

As there had been considerable agitation and discussion concerning the unsatisfactory condition of Lake Anthony for some time previous to the annual town meeting, at which place it was again brought under discussion, the board felt it their duty to bring the lake into as clean and healthful a condition as possible, and at the same time render it an ornament to the town. The board, therefore, consulting with several competent persons as to the most expedient and satisfactory way to obviate this difficulty, decided to close the opening to the lake, thereby changing the water from salt to fresh, and thus killing the peculiar growth of grass with which the lake was filled, and by its decay causing a disagreeable odor, rendering the shore unsightly and making the lake totally unfit for boating. We closed

the lake by the construction of a dam across the opening, by which means the water was changed from salt to fresh. We succeeded by this means in destroying the grass, as evidenced by the large quantities which came ashore during high winds, and the accumulation thus coming ashore was raked up and carted away as soon as possible.

#### DANVERS.

There was an epidemic of measles during the spring and summer, probably many more cases than were reported, as the disease is often so mild that no physician is called to attend.

The cases of diphtheria were treated with the new remedy, diphtheria antitoxin, of which so much has been expected. We have thought it advisable to keep an antitoxin syringe and a supply of antitoxin on hand, so that any physician in town can obtain them of the board of health at short notice.

The time is not far distant when the town must adopt a general sewage system, which is the only satisfactory way of disposing of the sewage in thickly settled parts of the town.

#### DEDHAM.

The town is to be congratulated, both in being able to obtain so excellent a service as will be hers when the metropolitan sewer is completed, and also in having the prospect of obtaining so speedy a relief from the extremely unsanitary conditions now prevailing in her midst. Upon the completion of the trunk sewer the town must construct a system of lateral or branch sewers to connect therewith, and some provision must be made for this purpose in the near future.

The keeping of swine in the town and the teaming of swill and offal through the streets seem to be an annual source of difficulty and nuisance.

#### EVERETT.

In July it came to the knowledge of the board that there were some unreported cases of diphtheria. The attending physician was prosecuted and fined fifty dollars in the district court. In these cases the probable source of infection was an old lounge that had been brought from out of town and upon which a child had died with diphtheria. It was put out in the yard, and the children had used it. Very soon there were 7 cases and 1 death in the neighborhood. Possibly there were other mild cases that were not recognized. There has been a number of cases since in that locality. In a number of instances we are quite sure that the disease has been contracted from infected persons from out of town or by children visiting infected houses in other places. In one case a child was sent here because its brothers had the disease. This child remained well, but a child in the

family where it came to stay developed a positive case of diphtheria. We have had a number of cases that have shown the great advantage of making bacteriological examinations. Of 26 cases where antitoxin was used early there were but 2 deaths (one of them occurred at the end of the sixth week), — a mortality of 7.7 per cent. In four cases it was used late, and the patients died. Of the 25 in which it was not used, 11 of the patients died.

Everett is a city of new, clean houses. We have a third less tuberculosis than the average of the State. By care and disinfection we can keep these houses free from the germs of this disease.

#### FALL RIVER.

Many cases of contagious diseases have come under our observation in homes and boarding-houses where there were not proper facilities for their care and isolation. We believe the safety of the public demands that some provision for such cases should be made, and would recommend that a ward in the old almshouse be set apart for the treatment of contagious diseases of this character, other than small-pox.

The increase in contagious diseases for the year, before noted, was altogether confined to scarlet fever and diphtheria, and was not wholly unexpected, as in the early spring and during the year those diseases were reported as prevalent, and even epidemic, in many cities of the Commonwealth as well as the surrounding States, from which the board knows some of the cases reported in this city were brought, and has reason to believe there were others.

Early in the year the board decided that it would be necessary to take energetic measures to stamp out those diseases, or prevent them becoming epidemic, and result in the closing of the public schools, as occurred elsewhere. Regulations were adopted, printed and furnished to all physicians and undertakers, and, through the superintendent of schools, the teachers of the public schools were also notified of the same.

In all cases of diphtheria, culture tubes are furnished by the board to the attending physician, to take cultures from the throat of the patient.

Our only protection against small-pox consists in thorough vaccination. This the board provides free of expense, and advertises freely, which we are gratified to note by the records is understood and appreciated by our metropolitan population, the number vaccinated each year exceeding the previous one. Vaccinations are performed by the clerk of the board, under the direction of the city physician. The number successfully vaccinated each year during the past four years was as follows: 1892, 1,326; 1893, 231; 1894, 1,720; 1895, 2,118.

While the primitive method of disposing of garbage, as pursued here, might for a time be permitted in a country town, where it could be conveyed to some uninhabited outlying district, it seems needless to add that

it is in no way adapted to a city of ninety thousand inhabitants. With a view to be able to suggest at this time the safest and most approved system of disposing of garbage, the board, agent and inspectors have visited different cities during the year, for the purpose of investigating their systems. The result of our inquiries confirms the opinion that destruction by fire is the only sure and safe method of disposing of garbage.

Ten cows were found to be infected with tuberculosis during the year, and, after the usual quarantine and inspections by the cattle commissioners, were destroyed, and the carcasses disposed of to the satisfaction of the board of health. In May last the board adopted a regulation requiring the owners of all neat cattle within the city to have the same duly registered and licensed at the office of the board of health every year. The reason that led to this was the number of cases coming to our notice of ill-fed cattle, allowed to roam through the streets and feed upon garbage among the different dumps throughout the city, as well as the filthy condition and lack of ventilation in the stables in which they were housed (when housed at all).

#### FITCHBURG.

House inspection has been extended, during the past year, over sections of the city contiguous to those sections inspected in 1894, and has included also the whole section, called the south Fitchburg district, which was the seat of the diphtheria epidemic. The total number of inspections recorded was 554.

The total number of nuisance complaints received by the board during the year was 148. This includes only the complaints of which a record is made. In connection with the regular house inspection, a very large number of minor unsanitary conditions were found and corrected by a personal notice.

The majority of the cases of diphtheria occurred in a section of the city which is in no way provided with sewers and proper means of drainage. It cannot be said, however, that the unsanitary conditions found in nearly every house where the disease occurred were the direct cause of the outbreak, as an infection from case to case was in nearly every instance traced. In all cases where defects were found the property owners were asked to correct them so far as possible, and in nearly every instance they readily and promptly complied. A very good map, showing the location of cases, accompanies the report.

Typhoid fever has been somewhat prevalent during the year, although the total number of cases was not greatly in excess of 1894. Out of a total number of 29 cases, 7 may fairly be said to have been imported,—the origin of the disease having been traced to infection arising in other places than Fitchburg. More than usual care has been exercised the past year in getting as accurate a history of each case as was possible.

## FRAMINGHAM.

The State Board of Health was consulted in reference to the cases of typhoid fever occurring in South Framingham, a suspected well of water was examined, and all infected premises ordered cleaned and disinfected. The outbreak could be traced to two imported cases.

## GARDNER.

The sanitary condition of the town is the best that it has been within our memory. Places that in former years were frequently neglected are now being regularly attended to, or are improved so as to avoid frequent complaints. We believe that prompt attention to complaints has led to this gratifying result, and the people of the town derive the benefit in being comparatively free from contagious diseases.

With a town of ten thousand inhabitants, the milk supply is one of great importance. Since the board recommended that those furnishing the supply should obtain licenses, we find that there has been a steady improvement in the care of stock, and, the natural result, an improvement in the milk supply. There have been forty-eight licenses granted during the past year.

## GLOUCESTER.

There have been more cases of scarlet fever and diphtheria during the past year than on some previous years, but the type has generally been mild.

The board would recommend the maintenance of a hospital for contagious diseases.

## HAVERHILL.

The most noticeable contrast in the mortality of any infectious disease between last year and previous years is the number of fatal cases of whooping-cough. Physicians are very careful to report their cases of diphtheria and scarlet fever, but little attention is paid to reporting cases of whooping-cough. The records show that only 34 cases have been reported, and of this number 12 deaths occurred last year. This would be more than 35 per cent. of the number reported, — a higher death rate than for any other disease that was reported to us. It is probable that, instead of there being but 34 cases, as reported, in the city last year, there were many more than that number. In the last twelve years, including 1895, there have been, in all, but 31 fatal cases of whooping-cough, an annual average of less than 3 deaths.

## HOLYOKE.

The board is of the opinion that a crematory necessary for the accommodation of the city's offal, and located in a convenient place, would be more economical to the city than the course now pursued.

Early in May a thorough health inspection of the city was made by the board of health. Several localities of doubtful healthfulness were promptly corrected in a measure satisfactory to the board. The importance of this annual sanitary inspection regularly and systematically carried out in the early season of each year cannot be over-estimated. It stimulates the habitually careless to a better regulation of their houses, and removes from unsanitary localities much that invites and fosters disease germs for summer activity. On persons not complying with the board's orders in regard to abating nuisance, eight sheriff's notices were served; conviction and fine was the result of each case.

Out of a mortality of 111 deaths during the month of July, 79 deaths were among infants.

## HYDE PARK.

About one hundred and fifty complaints have been received in relation to overflowing cesspools, vaults in bad condition, wet land, filthy houses and yards, dead animals, and swine kept without permits.

There has been quite an increase in the cases of contagious diseases, although in some respects we have fared better than some of the towns about us. The increase in cases of measles has given a large total for this year. We find that in cities and towns where a hospital is provided patients receive in most cases better care, the contagion is less liable to spread and deaths are less frequent. We hope the time will come when we can have this help in our work.

## IPSWICH.

During the months of October and November an epidemic of measles spread through the town. The disease was of a mild type, and no deaths occurred from the same. With these exceptions, the general health of the town has been fairly good. But how much longer this will continue is a question, and one to be seriously considered; for with our public water supply and our town being so situated in a valley, so to speak, and our drainage at the best none too good, the filth that will accumulate in numerous cesspools will prove a dangerous menace to the public health. The complaints to the board for the past year have been mostly from this cause, and absolute safety from cesspool filth will never be attained until the town provides a system of sewerage.

## LEE.

the board as a body, or by delegating one of its members, investigated complaints received regarding nuisances or conditions detrimental to the health whenever there seemed reasonable ground for such complaints; in all cases the recommendations or orders of the board were promptly and apparently cheerfully complied with.

## LEXINGTON.

In several years past the piggeries in various parts of the town have at times given considerable trouble. The present board, after careful consideration, adopted the system of giving permits for the keeping of swine, a practice which has thus far given very good satisfaction. The whole number of permits granted is sixteen, the board finding it unnecessary to issue permits for a less number than twenty pigs.

## LOWELL.

|                                |   |   |   |   |   |   |            |
|--------------------------------|---|---|---|---|---|---|------------|
| Cost of burning garbage, 1894, | . | . | . | . | . | . | \$5,742 69 |
| Cost of burning garbage, 1895, | . | . | . | . | . | . | 3,662 53   |
|                                |   |   |   |   |   |   | <hr/>      |
| Saving in 1895 of              | . | . | . | . | . | . | \$2,080 16 |

The ashes resulting from the combustion of our garbage have frequently been analyzed at the State Agricultural College at Amherst. The analyses show that to a certain extent summer ashes appear to be poorer than those of spring or fall. The largest amount of potassium oxide per 100 parts of ash found in a specimen of the ashes was 8.83; the largest amount of phosphoric acid was 32.36.

The only way to obtain a satisfactory solution of the problem, how to dispose of a city's garbage is to make a thorough personal investigation of all the methods now in use. Such an investigation has been made under the direction of Mr. Rudolph Hering, the well-known civil engineer, and chairman of the committee on disposal of garbage of the American Public Health Association.

At the same time, the conclusions reached by the board of health from a five-years study of the subject are briefly as follows:—

That reduction systems, even if well located, properly constructed and carefully managed, can at present offer no marked improvement over crematories.

That, at present, cremation is the best solution of the problem for the large New England city. That the kind of cremator to be selected

should have been in active operation for at least a year in some city where it has caused no nuisance.

That trustworthy figures should be obtained as to the average cost in fuel and labor to burn a ton of garbage, and that the price of fuel and labor should be known.

That that cremator should be selected which, considering the original cost, will do the city's work most efficiently and economically.

That it should be owned and operated by the city.

That the cremator now in use in Lowell is a vast improvement over the methods employed in all other New England cities.

A contagious disease hospital is recommended.

The board of health recommends, and the citizens can if they desire see, that Lowell is provided with a public bath-house.

As regards the use of antitoxin in diphtheria, we find from our limited experience somewhat more favorable results from the use of the remedy than by other means of treatment.

#### LYNN.

During the year there has been completed on Holyoke Street a hospital for contagious diseases, in accordance with chapter 511 of the Acts of 1894. This property was turned over to the board of health by the proper committee April 29, 1895. It was dedicated and opened to the admission of patients May 15, 1895, the administration building and two hospital wings, consisting of two wards each, receiving suitable furniture throughout as a gift.

The first patient was admitted June 13, and the total number admitted to Jan. 1, 1896, was 40. The first case of scarlet fever was admitted June 13, and the number of cases was 12. The first case of diphtheria was admitted August 14, and the number of cases was 27. One case of measles was admitted July 7. Of the 40 patients admitted, there have been 3 deaths, all from diphtheria, or about 11 per cent. of the diphtheria cases admitted, or a little more than 7 per cent. of total admissions.

As soon as possible after a patient suffering with diphtheria has been admitted to the hospital diphtheria antitoxin is administered, which has a pronounced curative effect upon the disease. The use of this remedy is responsible for making the mortality so low the past six months in this institution. In two of the patients that died the disease had been in progress six days before the remedy was administered. In the third patient, beside being a late stage of the disease, there was some complication which was not positively recognized. The first two patients died twenty-four and thirty-six hours after admission, and the third thirty-six hours after admis-

1. To my mind, all three of these patients could have lived had the administration of antitoxin been effected in the early stages. Comparing my experience with that had in 1893, when diphtheria appeared in the children's home, there were 3 deaths in 10 taken with the disease, or a mortality of 30 per cent.; this was before antitoxin was used in this country.

#### MARLBOROUGH.

There has been no serious outbreak of disease in the city during the year. In November a rather small epidemic of measles appeared, and about sixty cases were reported to the board.

The cases of scarlet fever and diphtheria were few and somewhat widely scattered in time of appearance and in location.

Early in the year the board discussed the matter of furnishing to the physicians of the city means for a culture diagnosis in cases of diphtheria. Although the opportunity to test the value of this method of being positive diagnosis in cases of contagious disease has been small, there being only a few cases of diphtheria during the year, the board is much pleased at the results of its experience. In the summer vacation a very severe case of diphtheria appeared, after an interval of five months in which no cases had been reported. By chance it was discovered that a boy who had lately come from a neighboring town, from a house where there was a case of diphtheria, was staying on the opposite side of the street. This boy had been dinner some days previous with the patient now sick with diphtheria. A culture examination of the throat of the suspected importer of the disease showed that his throat contained germs of diphtheria, though he had at any time been sick in bed nor in doors, nor had he paid any attention to his sore throat. No doubt he was the bearer of the disease to the aforementioned patient. These cases are mentioned to call the attention of the public to the fact, not generally understood, that a person may be suffering from diphtheria in a mild form, and not necessarily be sick in bed, but at the same time be capable of conveying the disease in its worst form to another individual.

The antitoxin furnished by the State Board of Health was used by the physicians attending diphtheria cases in only two instances. Each time there seemed to be a reluctance on the part of the physician to use the new remedy until other means of treating the disease had been tried. This is the course recommended by those who are familiar with the best results of antitoxin treatment, and it is hoped that physicians who decide to use antitoxin will give the remedy a fair trial by using it as early in the case as possible.

There were one hundred and seventy-one complaints of nuisances received during the year. These were promptly investigated. A few legal actions were served.

## MEDFORD.

In our report of 1894 attention was called to the fact that the existence of diphtheria can be positively recognized at an early stage by the modern methods of microscopical examinations. Following our recommendation, the sum of one hundred dollars for the special purpose of providing such examinations was generously granted, and during the past year thirty-one cultures from suspected cases of throat disease have been examined either at the Harvard or Tufts medical school laboratories, with the following results: number of examinations, 31. The bacillus of diphtheria was found in 23 examinations; the bacillus of diphtheria was not found in 8 examinations. It is thus to be seen that, of 74 cases reported as diphtheria, in fully 50 cases no microscopical examination was made.

In the opinion of this board, each report of a case of diphtheria, with its consequent discomforts of isolation, disinfection, etc., should be founded upon, and verified by, a proper microscopical examination.

## MELROSE.

Our requirements to correct nuisances have usually been promptly met. One person only has been brought to court and fined for offence, and he for not only emptying his cesspool himself without a permit, but for the gross misdemeanor of pouring the offensive material upon his neighbor's premises. A number of languid responses to our requirements have been wonderfully quickened by the impending resort to legal proceedings.

A concise summary of the labors of the inspector of plumbing during the past year is as follows:—

|                                           |           |     |
|-------------------------------------------|-----------|-----|
| Number of permits granted to do plumbing, | . . . . . | 492 |
| Number of permits for sewer connection,   | . . . . . | 166 |
| Number of visits made by inspector,       | . . . . . | 833 |
| Number of water tests made,               | . . . . . | 424 |
| Number of sewer connections tested,       | . . . . . | 129 |

## NEW BEDFORD.

For the past year every case of typhoid fever, diphtheria and scarlet fever has been investigated, with the idea of keeping a record of each case, and trying to impress upon the public the necessity of greater care in isolation and sanitation.

The school which each child attends is ascertained, together with the special room, and if several cases are found originating at about the same time in any one room, then that room is closed and thoroughly disinfected, and reopened again at the judgment of the board of health. Three times during the past year this has been done, probably stopping what at first

appeared to be the beginning of a serious epidemic of scarlet fever and diphtheria. The Sunday-school attended by the sick child is also inquired into, and the superintendent of that school notified of the fact of that child's illness, with the advice to stop future attendance of other children in the same family. Each case of scarlet fever is watched until desquamation has ceased, although no school permits are given until after four weeks have elapsed, even though that process should have apparently ceased earlier.

During the year about 550 calls have been made by the inspector. Nineteen vessels coming from foreign ports boarded by quarantine physician; none quarantined.

#### NEWTON.

Upon recommendation of His Honor the mayor, the city council, in June, appropriated the sum of one thousand dollars for the erection and maintenance of a bath-house on the bank of Charles River, off California Street, Ward 1. The committee on public property were instructed to erect the building, which, when completed, was to be turned over to this board to maintain.

The general health of the city during 1895 has compared favorably with previous years, the number of deaths being 448, a mortality of 16.23 per thousand. No general epidemic has occurred, although from some of the wards a large number of contagious cases were reported. The three important contagious diseases, diphtheria, scarlet fever and measles, have been present in the city almost continuously during the year, but never in such number as to cause serious alarm. As will be seen by the tables, the number of cases of diphtheria reported to the board was greatly in excess of the previous year.

The great benefit to the city of the contagious wards of the Newton Hospital has again been fully demonstrated, 121 cases of contagious disease having been admitted. The board has always urged, and in some cases compelled, parents to send their sick children to the hospital. This is one of those instances when the prerogative of the board seems to antagonize individual liberty; but it is the duty of a board of health to do all in its power to prevent the spread of a contagious disease, and, as by removing a sick person from a crowded tenement more can be done toward freeing the community from danger than can be accomplished by the strictest quarantine, the individual must yield to the community.

The plan of appointing medical inspectors for each ward or school district, on whom the board can call to examine the children in a school or elsewhere, in the event of suspected cases, has worked most satisfactorily. Several school inspections have been made, and a large number of children have been examined at their own homes by the inspectors; in several instances unsuspected cases of disease have been discovered and reported to

the board, thus enabling it to take proper precautions. No complaint in regard to the interference by the inspectors with the work of the family physician has been reported, and the board will continue the system during the coming year.

On Jan. 1, 1895, the board announced that it would furnish antitoxin free of charge to physicians who wished to use it in the treatment of diphtheria. Advantage was immediately taken of this offer, and the board continued to supply it until the State Board of Health was able to meet all demands.

The use of antitoxin in the treatment of diphtheria may be said to have become general in Newton after this offer made by the board. Previous to that several cases had been treated with it, but they were too few to permit any inference to be drawn as to its value. Since then the board has endeavored to keep careful statistics of the results of its use, and the figures given herewith are of great interest. To show most conclusively the effect of antitoxin upon the death rate in diphtheria, it is necessary to compare the rate in 1895 with that of previous years. Starting in 1890, it is found that the death rate from diphtheria in Newton is as follows:—

| YEAR.           | Cases. | Deaths. | Rate. |
|-----------------|--------|---------|-------|
| 1890, . . . . . | 55     | 10      | 18.18 |
| 1891, . . . . . | 42     | 7       | 16.66 |
| 1892, . . . . . | 29     | 8       | 27.50 |
| 1893, . . . . . | 88     | 32      | 37.27 |
| 1894, . . . . . | 81     | 20      | 24.69 |

The figures for 1895 are as follows:—

|                 |     |    |      |
|-----------------|-----|----|------|
| 1895, . . . . . | 151 | 15 | 9.93 |
|-----------------|-----|----|------|

In accordance with an order of the city council, the board considered the subject of establishing a steam plant for the disinfection of bedding, mattresses, etc., from houses infected with contagious disease. A report on this subject was made early in the spring, and the board again calls attention to the necessity for such a plant in order to prevent the spread of contagion through the inability of the board to properly disinfect such articles.

#### NORTHAMPTON.

We have no hospital for contagious diseases. A suitable location for one has been found in the rear of the almshouse property, across the track, safe from danger of contagion. A one-story wooden building costing but a small sum is needed in our city.

## NORTH ATTLEBOROUGH.

North Attleborough has enjoyed a comparative freedom from diseases of a contagious character during the past year. Any cases that have appeared have been quarantined at once, when the board has been notified of their existence. In each case, when quarantined, there has been no spread of the disease beyond the domicile where it first made its appearance. The neglect of one family in failing to ascertain the true character of the sickness of one of its members caused the board to fear that there might follow an epidemic of scarlet fever, since the child had been allowed to mingle with other children. Fortunately, only one other case followed as a result of this neglect. The board feels called upon to once more demand of parents that they should consult some competent authority in case of any suspicious sickness, especially among children.

## PROVINCETOWN.

The inspectors of the board of health have visited about eight hundred houses, and in nearly all found marked improvement in condition over last year. We have also visited the schools, and found the temperature quite even, but the system of ventilation very poor indeed, and would recommend that it be improved in some way during the coming year.

The vaccination law has been thoroughly enforced in our schools, with the result that over four hundred children have been vaccinated; each of these, together with all those who had been previously vaccinated, was resented with a certificate to be given to the superintendent, that a thorough and complete record may be kept of the same.

## QUINCY.

One of the earliest matters to receive the attention of the board was the importance of improving the scavenger system of the city. Complaints by citizens and the personal knowledge of the workings of the old system led the board to consider the desirability of adopting a more cleanly and responsible system than had previously prevailed. Testimonials and visits to neighboring cities where the contemplated system was in practical working order led the board to adopt the Odorless Excavating Company's system.

## SALEM.

In two cases this year it has been necessary to close schools until a complete disinfection could be had, and books, pencils, etc., likely to spread the infection, destroyed. So little did some persons realize the importance of thus protecting the children, that some adverse criticism followed because of the loss of the value of the books, which, however, was quite inconsiderable.

The board has encouraged in every practicable way the use of the new remedy, antitoxin, and with very gratifying results. The length of the disease, in cases where this remedy was used, has been much reduced, and in some cases lives have been saved which in all probability would have been lost under any other treatment. Of the four fatal cases, two were treated in this way and two were not.

#### SOMERVILLE.

|                                                                        |     |
|------------------------------------------------------------------------|-----|
| Number of nuisances abated, . . . . .                                  | 814 |
| Number of nuisances referred to board of 1896, . . . . .               | 173 |
| Number of nuisances complained of, . . . . .                           | 987 |
| Number of complaints (many covering more than one nuisance), . . . . . | 507 |
| Number of notices mailed, . . . . .                                    | 480 |
| Number of notices served by constables, . . . . .                      | 19  |

In addition to the above, many nuisances have been abated on verbal notice from the agent without action by the board, and of which no record has been made.

Six cases of glanders have occurred during the year. Prompt action was taken in every case, and the horses have been killed.

#### TAUNTON.

The board has advocated the isolation of suspected cases of diphtheria, especially where there are two or more children in the family or house, without waiting for a full development of the disease.

Early in the year the board of health invited the co-operation of the school teachers to aid in preserving the public health. To this end printed postal cards directed to the board of health were distributed to each teacher, whereon they were to indicate the absence of any pupil with suspected illness. Upon receipt of the card the physician of the board visited the scholar. A large number of cases so indicated have been examined, and, while a large majority of cases found were of the kind incident to childhood, suspicious cases of contagious disease have been found, the child isolated and children in the house kept from school.

#### WAKEFIELD.

Regulations for the inspection and testing of plumbing work were made and have been enforced. The result has been highly satisfactory, the quality of the work done being so much improved as to far outweigh the additional cost to the town of having the inspections made. We wish to impress upon the town the absolute necessity of some sewerage system in the very immediate future, as there are in certain portions of the town nuisances that cannot be entirely abated under present conditions.

## WALTHAM.

The careful precautions taken in regard to suspicious throat cases have been observed throughout the year. Cultures have been taken from all suspicious cases, at the request of the physician in charge, and quite a number of cases that would have passed as non-contagious were proved contagious and properly isolated.

No case of diphtheria has been let out of quarantine until a bacteriological test of the throat has proved the absence of the diphtheria bacillus. During the year 605 cultures have been taken, and the result of the bacteriological examination communicated to the physician in charge. The bacteriological laboratory of the Waltham Hospital has continued to serve the city by freely accommodating the board of health. There were 115 cases of diphtheria during the year, with 3 deaths, giving a very low mortality rate, which remarkable result was evidently due to the beneficial action of antitoxin, and also to the many mild cases which might have passed unnoticed but for the bacteriological test.

At the beginning of the present year this board notified the physicians of Waltham that free examinations of sputum for the bacilli of tuberculosis would be made by the physician of the board. As a result 52 specimens of sputum were sent to the board, and a careful microscopic examination made. The board also offered to disinfect after the death or removal of cases of consumption, when requested to do so by the physician in charge or the family.

In June, 1895, a somewhat different process of disinfection of rooms and furniture was begun. Reliance is no longer placed in fumigation, but in the most painstaking cleansing of every part of the room and furniture. Five per cent. solution of carbolic acid is used as a germicide. The city is in great need of a disinfecting station, where clothing and bedding can be disinfected by dry or superheated steam.

## WATERTOWN.

For the first time the care of all sanitary matters, which includes the bath-house, was assumed by the board of health. It was thought wise in the management of the bath-house to reserve it two afternoons a week for the use of women. For that purpose a woman was appointed to take charge of the bath-house during those afternoons. The plan has worked well and will be continued.

During the year the connection of all available premises with the common sewer has progressed very favorably. At every meeting of the board of health a number of premises have been ordered to be connected with the sewer, and almost uniformly the requests of the board have been complied with.

## WESTFIELD.

One hundred and eighty-nine nuisances have been abated during the year. Fifteen water-closets so located as to be considered nuisances have been ordered connected with the sewer.

We feel that the time has fully come when responsible persons should be employed to remove garbage from the streets and yards at least three times a week during the warm season.

## WESTFORD.

The use of antitoxin both as a cure and preventive of diphtheria has come into prominence and considerable use. We have been able to arrange for a supply from the State Board of Health through the city of Lowell, and in all necessary cases it can be used. Five patients have been treated with it during the year, with the following results: 2 cases membranous croup (diphtheritic), 1 recovery; 1 case diphtheria, recovery; 2 cases as a preventive, successful.

## WHITMAN.

During the past year seventy-three complaints were entered and attended to, thirty-six quarantine cards posted, and many other calls made and places investigated where no complaints have been made.

The row of dwelling-houses on Park Avenue, back of which lies Hobart's Pond, were nearly all found to be emptying their sink waste and sewage directly into the pond. Such a condition is in direct opposition to the laws of the State as well as public safety, hence the nuisance was discontinued.

## WOBURN.

The use of antitoxin was introduced and supplied free of charge to physicians who wished to use it in their practice. Its use has become general in Woburn, and the results are very satisfactory to the board. There is no doubt in the minds of the members of the board of health that its timely use has prevented an alarming death rate from diphtheria in Woburn during the last four months of the year.

## WORCESTER.

Number of complaints for the year ending Dec. 31, 1895, 1,602.

Nearly seven hundred cultures have been examined during the year, showing how largely physicians have availed themselves of the use of this department.

The city council selected and purchased a lot for an isolation hospital.

The office of the board is now open every day in the year; the hours Sundays and holidays are between 12 and 1 P.M. It was found necessary to make this addition to the office hours in order that the undertakers should be subjected to no delay in procuring burial permits, and also that culture tubes for diphtheria might be provided for and received from physicians.

The following group of figures presents the general death rate per 1,000, and the combined death rate per 10,000, from scarlet fever, diphtheria and croup, typhoid fever, cholera infantum and consumption, in a group of contiguous towns lying mostly in the metropolitan district, and for a period of four years, 1891-94. None of the number had a general death rate of more than 20 per 1,000, and the mean annual death rate of the group was 17.1 per 1,000 of the estimated living population.
